

PHYSICO-CHEMICAL TABLES

FOR THE USE OF
ANALYSTS, PHYSICISTS, CHEMICAL MANUFACTURERS,
AND SCIENTIFIC CHEMISTS.

IN TWO VOLUMES, EACH COMPLETE IN ITSELF.

BY

JOHN CASTELL EVANS, F.I.C., F.C.S.,
LATE SUPERINTENDENT OF THE CHEMICAL LABORATORIES AND LECTURER ON INORGANIC CHEMISTRY
AND METALLURGY AT THE FISHBURY TECHNICAL COLLEGE

VOLUME II.
PHYSICAL AND ANALYTICAL CHEMISTRY.

SECOND EDITION.

LONDON:
CHARLES GRIFFIN AND COMPANY, LIMITED,
EXETER STREET, STRAND, W.C.2.

1920.

PUBLISHERS' NOTE.

WITH the present volume of "Physico-Chemical Tables," which contains the concluding portions of the Tables of Physical Chemistry, the commencement of which will be found in Volume I., together with a valuable and exhaustive series of tables specially applicable to the operations of analytical chemistry, the work of the late John Castell-Evans is brought to a close.

The work in its present form may be regarded as a fitting monument to the energy, perseverance, and deep devotion of the author, who has not, unhappily, been spared to reap that harvest of gratitude which his labours have so truly merited from those who, like himself, have engaged in the furtherance of the Exact Sciences. But the work itself is a tangible record of the minute pains which the Author so assiduously brought to bear upon his life's work, and which shed lustre upon the College he so worthily served.

In a collection of tables of this nature it is almost inevitable that the individual worker in any special branch of applied chemistry will find much for which he may have no immediate or apparent use. On the other hand, it is seldom that, in compilations of this nature, even the individual worker can hope to find all that he requires. The aim of the Author of the present work has throughout been to provide not only every requisite for those engaged in the industrial applications of any given department of chemistry, but to supply the data required in *all* those departments, and to supply them thoroughly. From this point of view, the two volumes which constitute the present work may be regarded as absolutely unique.

It is at once the triumph of science and the despair of its votaries that the vast progress made from year to year, and, indeed, almost from day to day, soon renders the theories of yesterday obsolete and challenges the most careful investigations and calculations of the past. The physical constants, the atomic weights, and the fundamental units upon which all accurate calculations must necessarily be based, are at all times undergoing minute and painstaking revision by experts who bring to the elucidation of the problems involved the newer methods and the most accurate appliances which the progress of science has placed at their disposal. The process of revision tends always towards perfection, and the data now placed in the hands of scientific workers are

believed to be as near perfection as time and circumstances will allow, the investigations of the leading scientists all over the world and the results of the most recent physical and chemical investigation having been laid under contribution in order to secure that accuracy and precision which alone can justify the existence of a work of this nature. Indeed, so careful was the Author to ensure that his work should possess the utmost degree of accuracy, that he was, to the last, engaged in the recalculation of numerous tables which had appeared in the earlier volume, in the light of later research; and in the Supplementary Tables which appear at the end of the present volume will be found all the material necessary for bringing the numerical results into accordance with the "Orders in Council" and the Regulations issued by the Board of Trade as recently as March 1907.

Of the value of the work as a whole there can be no two opinions. The tables now collected together in handy compass and arranged so that the maximum convenience of reference in their consultation has been attained, are at once more numerous and more copious than any similar collection of tables previously published, while their selection and arrangement has been such as to render the invaluable data they contain most readily accessible. The Publishers venture, therefore, to hope that the welcome accorded the earlier volume may be extended to the present volume, and that those for whom the work has been prepared will find it of such general use and assistance that it may be truly felt, by all concerned, that the labours of the late distinguished author have not been in vain.

NOTES ON THE USE AND APPLICATION OF THE MOST IMPORTANT TABLES.

PART III.—PHYSICS—*continued.*

Table LXX. — Molecular Dynamics.

In this table will be found all the data necessary for the calculation of the volumes and pressures of gases by formulæ which combine Charles' or Boyle's law and Gay-Lussac's law, and are the outcome of Avogadro's original hypothesis respecting the relation of the number of gaseous molecules to the volumes they occupy.

The succeeding table, LXXA., gives values of U and P for various gases, and is followed by data relating to molecular speeds, according to Meyer. Table LXXB. deals with the subject of the speed of sound waves in a medium, and is followed by tables which give the speed of sound in gases, in liquids, in solutions and mixed liquids, in solids, and in dry air.

Table LXXII. gives the values of N for simple liquids, and embodies the figures for a large number of organic liquids, the values of mixed liquids and solutions being further continued in Tables LXXII.2, LXXII.3, 3A, 3B, 3C, 3D, and 3E.

The absolute viscosities of water, alcohol, and bromine are made the subjects of the next three tables, and the specific viscosities of a large number of compounds are given in the remaining tables relating to this section. The molecular volumes of liquids are given in Table LXXP.

Table LXXI.—Capillarity and Surface Tension.

This is the commencement of a series of tables relating to capillarity and surface tension, including the capillarity constants of water, alcohol, benzol, acetone, carbon disulphide, and ether, and the surface tension of the first four substances. These tables are amplified in LXXIa. for a number of other substances, whilst the relations between surface tension and temperature will be found in Table LXXIb. The surface tension of solids, given in a short table

relating to Laplace and Van der Waall's constants will be found in Tables LXXIs. and LXXIr.

Table LXXII.—Physical Properties of Solutions.

The next series of tables gives the physical properties of solutions, and is distributed into sub-tables, giving the boiling points and concentration of aqueous solutions, the vapour tension and boiling points of aqueous solutions of glycerol, and comprehensive specific gravity tables of ammonia solutions and solutions of the caustic alkalies, carbonates, and commercial acids, followed by tables of specific gravities of the solutions most commonly employed in chemical operations. These tables will be found exceedingly useful in chemical works and in dye works or bleaching establishments.

The solubility of gases will be found in Table LXXIII.

Table LXXIV.—Molecular Weights.

The various methods of ascertaining molecular weights have been given at considerable length, including the cryoscopic method, the boiling method, and the distillation of mixed liquids. The tables will be found exceedingly useful for those engaged in the atomic weight determinations and the observation of paper densities.

PART IV.—ANALYTICAL CHEMISTRY.

In the tables given in this, the concluding portion of the work, the values of the atomic weights adopted in the calculations are those of the International Committee, as issued in 1904, and for all ordinary purposes these may be regarded as substantially correct.

Table LXXV. may be commended to the use of analysts, as by its means they will be able to compute the results of the weighing in of the end-products of gravimetric methods by a simple inspection of the columns. The list of factors includes nearly every substance likely to be required in analytical operations, the logarithms and the factors being, in every case, given to seven figures. The table covers forty-two pages and is for use in volumetric analysis. The remaining tables of this series are applicable to gas and water analysis, to acidimetry, alcoholometry, and all the ordinary volumetric operations.

Table LXXVI. will be found useful in breweries and distilleries, as well as in the laboratories of public analysts and in those used for excise work, as they give extensive readings of the alcoholometer and figures for the dilution of alcohol, with the estimation for specific gravity of aqueous solutions. The mass and volume of absolute alcohol between 0 and 20 degrees C., as calculated by Winkler and Mendelejeff respectively, are given in the concluding tables of this series.

Tables LXXVII. and LXXVIII. These tables give the weight of various substances in various aqueous solutions, and will be found useful in local analysis and for the purposes of the physiological laboratory.

SUPPLEMENTARY TABLES.

The Supplementary Tables give a recalculation of weights and measures in accordance with the "Orders in Council" and Regulations issued by the Board of Trade in March 1907. As these figures supersede those given on pages 48-53, Vol. I., careful note should be taken in all calculations requiring extreme accuracy to substitute the latter and more authoritative values

PART III.—PHYSICS.—*Continued.*

TABLE LXX.—Molecular Dynamics, Kinetic Theory of Gases, etc

If P	denote the pressure per unit area in dynes,
V	„ volume of gas in centimetre cubes,
m	„ mass of each individual molecule in grammes,
U	„ mean velocity of molecules in centimetres per second,
N	„ number of individual molecules in V cm. cubes of the gas.

$$P = \frac{NmU^2}{3V}$$

or putting $n = \frac{N}{V}$ = number of molecules in 1 cm. cube,

and $\rho = nm$ = mass of 1 cm. cube of the gas,

$$P = \frac{1}{3}\rho U^2$$

$$\text{and } U^2 = \frac{3P}{\rho} \quad \text{or } U = \sqrt{3P/\rho}.$$

$$\text{For all gases } T \propto \frac{mU^2}{2}$$

that is, at the same temperature the mean kinetic energy of molecular agitation is practically the same for all gases : or

$$m_1U_1^2 = m_2U_2^2 = m_3U_3^2 = \text{etc.}$$

Under the same pressure we have—

$$P = \frac{N_1m_1U_1^2}{3V_1} = \frac{N_2m_2U_2^2}{3V_2} = \frac{N_3m_3U_3^2}{3V_3} = \text{etc.}$$

the temperature, $m_1 U_1^2/3 = m_2 U_2^2/3 = m_3 U_3^2/3$,

$$\text{therefore } \frac{N_1}{V_1} = \frac{N_2}{V_2} = \frac{N_3}{V_3} = \text{etc.}$$

$= V_3 = \text{etc.}$

we get $N_1 = N_2 = N_3 = \text{etc.}$

Avadro's law that "under like conditions as to temperature and pressure, equal volumes contain the same number of gaseous molecules."

On the thermodynamic scale of absolute temperature we get—

$$T = \frac{2}{3} m U^2 \text{ and } m U^2 = \frac{T}{\frac{2}{3}}$$

$$\therefore P = \frac{N}{3V} \cdot \frac{T}{\frac{2}{3}} \quad \text{that is } PV = \frac{N}{3} \cdot T$$

or putting $\frac{N}{3} = R$, we get $PV = RT$,

constant.

Boyle's Law.—When T is constant $PV = \frac{R}{T} = R_1$ a constant, or the volume varies inversely as the pressure.

Charles's Law.—When P is constant $\frac{V}{T} = \frac{R}{P} = R_2$ a constant, *i.e.*, the volume varies directly as the absolute temperature.

In the preceding equations we virtually consider the molecules as mere points, having each a negligible volume, but practically occupying no space; the deductions are therefore only approximate to the truth.

XXA. in columns 4 and 6 on pp. 553-4, V denotes the volume in litres of a gramme molecule; in the corresponding columns on pp. 555-6 the same denotes the volume in cubic feet of a British mol, *i.e.*, a pound-molecule Avordupois.

(C.R. cxiii. 186) the following values of V under 760 mms.—

For hydrogen,	22.41 litres
„ oxygen,	22.39 „
„ nitrogen,	22.34 „
Mean value,	22.38 „
giving $R = 0.0819$.	

under 760 mms. at 0°C. we get from the data given on p. 308, *ante*, the following values for V :—

For air	$V = 0.7732768$ litres
„ hydrogen	$V = 11.1279266$ „
„ oxygen	$V = 0.6997930$ „

So when P is given in grammes per centimetre square and V in litres, we have for 1 gram. of air at 0° C.—

$$PV = 1033 \cdot 2428 \times 0 \cdot 7732768 \text{ litres} \\ = 798 \cdot 982677$$

When P is given in dynes per cm², $PV = 783476 \cdot 7287$

Taking 0° C. \equiv 273° on the absolute thermodynamic scale of temperature we get for 1 gram. of air (V being expressed in litres)—

P expressed in atmospheres,	R =	0·0028325
„ mms. of Hg,	R =	2·1527119
„ grms. per cm ² ,	R =	2·9266765
„ dynes per cm ² ,	R =	2869·8781272

and for 1 gram. of hydrogen —

P expressed in atmospheres,	R =	0·0407616
„ mms. of Hg,	R =	30·9788431
„ grms. per cm ² ,	R =	42·1166670
„ dynes per cm ² ,	R =	41299·3039973

and for 1 gram. of oxygen—

P expressed in atmospheres,	R =	0·002563344
„ mms. of Hg,	R =	1·948141688
„ grms. per cm ² ,	R =	2·648557070
„ dynes per cm ² ,	R =	2597·15621928

For an ideal gas 1 gram. of which, at 0° C. under a pressure of 760 mms. of mercury, would occupy exactly one litre, we have—

P expressed in atmospheres,	R =	0·003663
„ mms. of Hg,	R =	2·783882
„ grms. per cm ² ,	R =	3·7847721611
„ dynes per cm ² ,	R =	3711·3206544176

For an ideal gas 1 gram. of which, at 0° C. under a pressure of 1 metre of Hg, occupies one litre, we have—

P expressed in atmospheres,	R =	0·00278388
„ mms. of Hg,	R =	2·1157509157
„ grms. per cm ² ,	R =	2·8764268425
„ dynes per cm ² ,	R =	2820·6036973574

If R_a denote the value of R for any gas A under any given conditions, and R_b the value for any other gas B under the same conditions, then $R_b = R_a / \Delta$ where—

$$\Delta = \frac{\text{mass of 1 litre of B}}{\text{mass of 1 litre of A}}$$

Nernst gives—

$$C_p - C_v = \frac{PV}{T} = R \text{ in calories;}$$

where C_p = molecular heat of gas under constant pressure, and

C_v = „ „ at constant volume.

1 'litre-atmosphere' = 1033000 c.grm. units of works

= (1033000/42750) calories = 24·17 calories

and as $R = 0 \cdot 0819$ litre-atmosphere, he gets $R = 1 \cdot 980$ calories = 2 calories very nearly.

Ostwald gets $C_p - C_v = 84688$ c.grm. units of work, and $84688/42355 = 2$ calories very nearly.

These values work out a little different when the most recent values are taken for the weights of the various gases and for J : thus for oxygen we get

$$\begin{aligned} C_p - C_v &= 84119 \text{ c.grm. units of work} \\ J &= 42740 \\ (C_p - C_v)/J &= 1.963 \text{ calories} \end{aligned}$$

so for all ordinary gases and for a large number of vapours the approximation 2 calories is considerably too high.

In the Table LXXA. the values of R for Fahrenheit temperatures can be easily calculated from those given by simply multiplying by $5/9$, *i.e.*,

$$R_F = R_C \left(\frac{1}{2} + \frac{1}{9} \text{ of } \frac{1}{2} \right).$$

Thus, R_C for hydrogen = 0.08152 under one atmosphere.

$$\frac{1}{2} \text{ of } 0.08152 = 0.04076$$

$$\frac{1}{9} \text{ of } 0.04076 = 0.00453 \text{ very nearly}$$

$$\therefore R_F = 0.04529.$$

In the table the standard of molecular weights has been taken as $H_2 = 2$; the values of V and R for the standard $O_2 = 32$ can be easily calculated by multiplying those in the table by $\frac{32}{2} = 16$. Putting V_H for value corresponding to $H_2 = 2$, and V_O for value corresponding to $O_2 = 32$, we get

$$V_O = V_H + A + B + C + D + E + F$$

where $A = V_H \div 150$, $B = A \div 8$, $C = B \div 15$, $D = C \div 50$, $E = D \div 140$, and $F = E \div 18$.

Thus for V under 1 grm. per cm². we get

$$\begin{aligned} V_H &= 22995.7 \\ A &= 153.3 \\ B &= 19.2 \\ C &= 1.3 \end{aligned}$$

$$\therefore V_O = 23169.5$$

The instances in which it will be found necessary to proceed beyond C will be very few.

TABLE LXXA.—Values of \bar{V} and R for various Gases.

Substance.			P in Atmospheres 760 mms. of Hg.		P in Metres of Ice-cold Hg.	
Name.	Formula.	Molec. Weight.	\bar{V}	R	\bar{V}	R

Molecular Speeds.

The expression $U = \sqrt{3P/\rho}$ gives us "that speed which all the molecules would have if, without addition or subtraction of energy, the speeds of all were made equal," i.e., U is simply the square root of the mean of the squares of all the individual speeds, or if n be the number of molecules and $U_1, U_2, U_3, \dots, U_n$ be the individual speeds of each molecule respectively, then

$$U^2 = \frac{1}{n}(U_1^2 + U_2^2 + U_3^2 + \dots + U_n^2)$$

The value U thus calculated (generally denoted by G by German writers) is neither the mean velocity nor the most probable velocity of molecular agitation.

O. E. Meyer gives

$$\Omega = \text{The arithmetical mean value of the speeds} = U\sqrt{8/3\pi}.$$

$$W = \text{The most probable value of the speed} = U\sqrt{2/3}.$$

$$\text{and } O = \text{The mean probable value of the speed} = 1.0875W.$$

$$\text{Now } \Omega = \frac{1}{n}(U_1 + U_2 + U_3 + \dots + U_n)$$

$$\text{and therefore } \Omega^2 = \frac{1}{n^2}(U_1^2 + U_2^2 + U_3^2 + \dots + U_n^2 + 2U_1U_2 + 2U_1U_3 + \dots + 2U_{n-1}U_n)$$

$$\text{so } \Omega^2 < \frac{1}{n}(U_1^2 + U_2^2 + U_3^2 + \dots + U_n^2)$$

$$\text{i.e., } \Omega^2 < U^2.$$

According to Maxwell's law :—

$$\Omega = 4\pi^{-1/2}(km)^{1/2} \int_0^\infty d\omega \cdot \omega^3 e^{-km\omega^2} = 2(\pi km)^{-1/2}$$

Now the mean kinetic energy of molecular agitation is

$$E = \frac{1}{2}mU^2 = 2\pi^{-1/2}km^{1/2} \int_0^\infty d\omega \cdot \omega^4 e^{-km\omega^2} = \frac{3}{4k}$$

and therefore

$$U = \sqrt{3/2km}$$

$$\therefore \Omega : U = \sqrt{4/\pi km} : \sqrt{3/2km}$$

$$\Omega/U = \sqrt{8/3\pi} = 2\sqrt{2/3\pi} = 0.9213177319.$$

Now the most probable value of the speed is according to Maxwell's law :—

$$W = \frac{1}{2}\pi^{1/2}\Omega = U\sqrt{2/3} = U \times 0.8164965809 \\ = \Omega \times 0.8862269255.$$

Putting $\psi = O/W$, Meyer gets—

$$\frac{1}{3}\pi^{1/2} = \int_0^\psi d\psi \cdot \psi^2 e^{-\psi^2}$$

and from this he calculates—

$$\psi = 1.0875 \text{ nearly.}$$

Thus we get—

$$\begin{aligned} U &= \sqrt{3P/\rho} = \Omega \times 1.085402 = W \times 1.224745 = O \times 1.126202 \\ \Omega &= U \times 0.921318 = W \times 1.128379 = O \times 1.037590 \\ W &= U \times 0.816497 = \Omega \times 0.886227 = O \times 0.919540 \\ O &= U \times 0.887940 = \Omega \times 0.963772 = W \times 1.0875. \end{aligned}$$

Meyer, from Jolly's values for ρ for oxygen and nitrogen, calculated that at 0° C. for

Oxygen, $U = 461.2$ metres per $1''$; $\Omega = 424.9$; $W = 376.6$ and $O = 409.5$

Nitrogen, $U = 491.7$ metres per $1''$; $\Omega = 453.0$; $W = 401.4$ and $O = 436.6$.

When B is given in millimetres of ice cold mercury, at sea level in latitude 45° , we get

$$P = \text{Pressure in dynes per cm}^2. = 1333 \cdot 14676139 \times B$$

and when $B = 760$

$$P = 1013190 \cdot 538656$$

$$U = \sqrt{3P/\rho} = \sqrt{3999 \cdot 11028417 \times B/\rho} = 63 \cdot 241128 \sqrt{B/\rho} \text{ cms. per sec.}$$

when $B = 760$

$$U = \sqrt{3039571 \cdot 615968/\rho} = 1743 \cdot 436726 \sqrt{1/\rho} \text{ cms. per sec.}$$

For an ideal gas, 1 grm. of which occupies 1 litre under a pressure of 1 atmosphere - 760 mms. of Hg = 1013190·538656 dynes per cm^2 , we get

$$U = 55132 \cdot 310 \text{ cms. per sec.}$$

$$\Omega = 50794 \cdot 375 \quad , \quad ,$$

$$O = 48954 \cdot 184 \quad , \quad ,$$

$$W = 46015 \cdot 342 \quad , \quad ,$$

For an ideal gas 1 grm. of which occupies 1 litre under a pressure of 1 metre of Hg = 1333146·76139 dynes per cm^2 , we get

$$U = 63241 \cdot 097 \text{ cms. per sec.}$$

$$\Omega = 58265 \cdot 144 \quad , \quad ,$$

$$O = 56154 \cdot 300 \quad , \quad ,$$

$$W = 51636 \cdot 139 \quad , \quad ,$$

For an ideal gas 1 grm. of which occupies 1 litre under a pressure of 1 megadyne per cm^2 , we get

$$U = 54772 \cdot 256 \text{ cms. per sec.}$$

$$\Omega = 50462 \cdot 651 \quad , \quad ,$$

$$O = 48634 \cdot 477 \quad , \quad ,$$

$$W = 44721 \cdot 360 \quad , \quad ,$$

For air at 0°C. , we get

$$U = 48481 \cdot 235 \text{ cms. per sec.}$$

$$\Omega = 44666 \cdot 621 \quad , \quad ,$$

$$O = 43048 \cdot 428 \quad , \quad ,$$

$$W = 39584 \cdot 767 \quad , \quad ,$$

For hydrogen at 0°C. , we get

$$U = 183913 \cdot 376 \text{ cms. per sec.}$$

$$\Omega = 169442 \cdot 654 \quad , \quad ,$$

$$O = 163304 \cdot 045 \quad , \quad ,$$

$$W = 150164 \cdot 642 \quad , \quad ,$$

And for oxygen at 0°C. , we get

$$U = 46120 \cdot 179 \text{ cms. per sec.}$$

$$\Omega = 42491 \cdot 339 \quad , \quad ,$$

$$O = 40951 \cdot 952 \quad , \quad ,$$

$$W = 37656 \cdot 968 \quad , \quad ,$$

Assuming that oxygen is 15·884 times as heavy as hydrogen, Meyer gets the following values for the calculated speeds of hydrogen molecules at 0° C.—

$$\begin{aligned} U &= 1838\cdot2 \text{ metres per second.} \\ \Omega &= 1693\cdot6 \quad " \quad " \quad " \\ O &= 1632\cdot2 \quad " \quad " \quad " \\ W &= 1500\cdot9 \quad " \quad " \quad " \end{aligned}$$

TABLE LXXB.—Values of U, Ω , O and W, according to O. E. Meyer.

Iodine,	I ₂	8·716	164	151	146	134

The values of O and W are calculated by the compiler from Meyer's numbers.

By substituting for $1/\rho$ its value, the volume in centimetre cubes occupied by 1 gram. of the gas, we avoid the process of division.

When any number of gases exert the same pressure, P , we have

$$U_a^2 : U_b^2 : U_c^2 : \dots = \frac{3P}{\rho_a} : \frac{3P}{\rho_b} : \frac{3P}{\rho_c} : \dots = \frac{1}{\rho_a} : \frac{1}{\rho_b} : \frac{1}{\rho_c} : \dots$$

That is, when exerting the same pressure the mean square of the molecular speeds is inversely proportional to the density.

$$U_b = U_a \sqrt{\rho_a/\rho_b}$$

or if s = specific gravity of gas ρ_b referred to gas ρ_a as unity

$$U_b = U_a / \sqrt{s}.$$

Putting M for the molecular weight of a gas we get ($H_2=2$)

$$V/M = \text{volume in litres occupied by 1 gram. of the gas,}$$

so at 0°C.

$$U = \sqrt{3039571615 \cdot 968 \times V/M} = 260092 \cdot 791 / \sqrt{M}$$

or putting s_a = specific gravity referred to air as unity, we get for 0°C.

$$U = 48481 \cdot 235 / \sqrt{s_a}$$

At the same temperature $mU^2/2$ is the same for all gases, so for the same gas—

$$U_1^2 : U_2^2 : U_3^2 : \dots = T_1 : T_2 : T_3 : \dots$$

$$\text{so } U_t = U_0 \sqrt{1 + at}.$$

DISTRIBUTION OF SPEEDS, ETC.

According to Maxwell's law the curve representing the propable distribution of molecular speeds has the equation—

$$y = 4\pi^{-\frac{1}{2}}x^2e^{-x^2}.$$

And the arithmetical mean value —

$$\Omega = 4\pi^{-\frac{1}{2}}(km)^{\frac{3}{2}} \int_0^{\infty} d\omega \cdot \omega^3 e^{-km\omega^2} = 2(\pi km)^{-\frac{1}{2}}$$

where $km = \rho/2P$, so

$$\Omega = \sqrt{\frac{8P}{\pi\rho}} = \sqrt{P/\rho} \times 1.5957691216.$$

Out of every N molecules, if n represent the number which move with a velocity w in a direction making angles ς and ϕ with reference to a fixed axis, and if the gas have a velocity of translation = o then,—

$$n = N(\pi^{-1}km)^{\frac{3}{2}} e^{-km(\omega^2 - 2\omega o \cos \varsigma + o^2)} \omega^2 d\omega \sin \varsigma d\varsigma d\phi.$$

And if ν = number of all that move with a velocity between w and $w + dw$ we get

$$\nu = N(\pi^{-1}km)^{\frac{3}{2}} \omega^2 d\omega \int_0^{2\pi} d\phi \int_0^{\pi} d\varsigma \sin \varsigma e^{-km(\omega^2 - 2\omega o \cos \varsigma + o^2)},$$

and if the gas have no motion of translation :—

$$\nu = 4N\pi^{-1}(km)^2\omega^2e^{-km\omega^2}l\omega.$$

This will give a maximum value for ν when $km\omega^2 = 1$, and the value of ω which gives this result will be the most probable velocity, i.e., $\omega = W$.

$$\therefore (\rho/2P)W^2 = 1 \text{ and } W^2 = 2P/\rho$$

$$W = \sqrt{P/\rho} \times 1.4142135624$$

And as already stated,—

$$U = \sqrt{P/\rho} \times 1.7320508076.$$

O. E. Meyer finds that for oxygen at 0° C.—

$$W = 376.6 \text{ metres per second ;}$$

and he calculates that out of every 1000 molecules—

13 to 14 molecules have a speed below				100 metres per second			
81	82	"	"	between 100 and 200	"	"	"
166	167	"	"	" 200	" 300	"	"

With the usually accepted atmosphere ≈ 760 mm. of ice cold mercury $= P = 1013190.538656$ dynes per cm. square, we get—

$$U = 1743.436725/\sqrt{\rho}$$

$$\Omega = 1606.259169/\sqrt{\rho}$$

$$O = 1548.067261/\sqrt{\rho}$$

$$W = 1423.510125/\sqrt{\rho}$$

TABLE LXXE.—Speed of Sound Waves.

Closely connected with the speeds of the molecules is speed of sound waves in a medium. Newton's formula for the speed of sound waves—

$$\omega = \sqrt{e/v}$$

where e = elasticity of substance, and v = volume of unit mass, gave results considerably too low. By introducing into this expression Laplace's correction we get the equation—

$$\omega = \sqrt{\kappa e/v}$$

which is sufficiently accurate for all practical purposes ; here $\kappa = c_p/c_v$ as before.

For gases we may take $e = P$, and for all substances $v = \frac{1}{\rho}$; the Newtonian formula then becomes

$$\omega = \sqrt{P/\rho}$$

and the corrected expression—

$$\omega = \sqrt{\kappa p / \rho} \text{ or } \omega^2 = \kappa p / \rho.$$

We have already seen that—

$$U^2 = 3P/\rho$$

therefore—

$$\omega^2 = U^2 \cdot \frac{\kappa}{3} = \Omega^2 \cdot \frac{\pi \kappa}{8}.$$

Now if λ be the length of a sound wave, and n = the number of vibrations per second, then

$$\omega = n\lambda$$

and as n and λ can be experimentally determined, we have an almost direct method of determining ω , and consequently U and Ω .

For most gases (*i.e.*, all with diatomic molecules) we may put $\kappa = 1.405$ and

$$\omega = 1.1853 \sqrt{P/\rho} = 0.68435 U = 0.7427935 \Omega.$$

As to the variation of ω with change of temperature, we get (theoretically)

$$\omega_t = \omega_0 \sqrt{1 + \alpha t} = \omega_0 \sqrt{1 + 0.00367 t} = \omega_0 (1 + 0.001835 t), \text{ where } t \text{ is comparatively small.}$$

For air at 0°C . we got $U = 48481$ cms. per second ;

$$\therefore \omega = 33178 \text{ cms. } ,, \quad ,, \quad = 1089 \text{ ft. per second.}$$

It will be seen that this agrees very closely with the experimental results given in Table LXXV.

The expression

$$\omega_t = \omega_0 \left(\sqrt{1 + \alpha t} \right) = \omega_0 \left(1 + \frac{\alpha t}{2} - \frac{1.1}{1.2} \left(\frac{\alpha t}{2} \right)^2 + \frac{1.1 \cdot 3}{1.2 \cdot 3} \cdot \left(\frac{\alpha t}{2} \right)^3 - \frac{1.1 \cdot 3 \cdot 5}{1.2 \cdot 3 \cdot 4} \cdot \left(\frac{\alpha t}{2} \right)^4 + \text{etc.} \right)$$

gives us very nearly 1 ft. as the change in velocity for every degree Fahrenheit change in temperature.

Airy gives ω at $0^\circ \text{F.} = 1050$ ft. per second, which works out, with the increment of 1 ft. per degree, to 1082 ft. at the melting point of ice. Stone's experiments gave, as a mean value, that ω at $32^\circ \text{F.} = 1090.6$ ft. per second.

Where r is affixed to numbers in cols. 3 and 4, it denotes that they have been calculated from the corresponding numbers in the other column.

In this table κ is taken as 1.405 for gases composed of diatomic molecules; for all others the values are taken from experimental results.

* In all cases where an asterisk is inserted in col. 3, the numbers give the velocity of sound in pipes filled with the gas or vapour: this is never quite the same as in a large mass of the gas. Von Helmholtz gives the formula

$$\omega = \omega_1 \left(1 - \frac{C}{D \sqrt{N}} \right)$$

where ω = Velocity of sound in tube filled with gas.

ω_1 = Velocity of sound in large, practically unconfined, mass of gas.

D = Diameter of tube.

N = Frequency of the note sounded.

C = A constant which, according to v. Helmholtz, has a value depending only on the friction coefficient of the gas, but according to Kirchhoff it depends on other things as well.

The velocity of sound also depends on the intensity, but the law relating to this has not been satisfactorily indicated.

TABLE LXXII.—Velocity of Sound in Liquids.

have, for all substances,—

$$\omega^2 = E_\phi / \rho$$

E_ϕ represents the adiabatic elasticity.

ing E_θ for the isothermal elasticity, which can be determined by direct experiments, E_ϕ —

$$E_\phi / E_\theta = c_p / c_v = \kappa.$$

for liquids,—

$$c_p - c_v = \alpha^2 V T E_\theta$$

$$\therefore c_v = c_p - \alpha^2 V T E_\theta$$

α = Co-efficient of cubical expansion,

V = Volume of unit mass,

T = Absolute temperature.

quantities c_p , E_θ , α and V being determined experimentally, we can easily calculate c_v .

water at the point of maximum density (practically = 4° C.) we must have $\alpha = 0$, consequently $c_p = c_v$ and $E_\phi = E_\theta$.

Therefore at 4° C.

$$\omega \text{ in water} = \sqrt{E_\theta / \rho}$$

in absolute units, = 2.03×10^{10} practically, and $\rho = 1$

so ω in cms. per second = $\sqrt{20300000000} = 142478$

velocity at 0° C. would be higher, as α would then be negative.

TABLE LXX₃.—Velocity of Sound in Solids.

In cords and thin bars we may have lateral shrinkage or expansion accompanying longitudinal disturbances, and in such cases—

$$\omega = \sqrt{\frac{E}{\rho}} \quad \text{where } E = \text{Modulus of Elasticity (see Table XIX.)}$$

$$E = \frac{9CK}{3K + C} \quad (\text{see Table XIX.})$$

In solids extended in every direction we may have sound waves, *i.e.*, waves of longitudinal disturbance, propagated with the velocity:—

$$\omega = \sqrt{\frac{3K + 4C}{3\rho}}$$

For rods where the diameter is very great we have from the first equation given in this sub-section—

$$E = \rho\omega^2$$

We can by Kundt's dust method determine ω in rods and bars with a fair degree of accuracy, and ρ being easily ascertained, we can thus make very close approximations to the value of E .

The values in the following table marked with an asterisk are calculated on the supposition that the velocity of sound in air at 0° C. is 332·412 metres per second: the original investigators gave their results in terms of the velocity in air.

TABLE LXXG. - *continued*.

(3) Variation of η with Temperature.

We have, as we shall see a little further on,

$$\eta = \kappa \rho \Omega L_n$$

where κ is a constant, the value of which has been calculated by the late Wilhelm Coman as 0.30967, and L is the length of the mean free path of the molecules of a gas. In gases L varies as the absolute temperature very nearly, and $\Omega \propto \sqrt{T}$. From this we get Sutherland's deduction that

$$\eta \propto T^{\frac{1}{2}}$$

or

$$\eta = \eta_0(1 + at)^{\frac{1}{2}}$$

O. E. Meyer puts this in the form -

$$\eta = HT^{\frac{3}{2}}$$

where $H = \eta_0/T_0^{\frac{3}{2}}$

By the aid of this formula Meyer calculated the following values for H from Schumann's determinations of the value of η at the various temperatures:—

	T°	H
Benzol,	19.0	0.01552
	70.1	1552
Methyl formate,	100	1597
	20	1815
Methyl <i>i</i> -butyrate,	100	1841
	21	1476
Ethyl propionate,	65.5	1656
	100	1561
Propyl acetate,	16.1	1530
	68.6	1673
Iso-butyl formate,	99.9	1616
	15	1524
Iso-butyl acetate,	77.8	1455
	100	1521
Puluj between 3° and 30° C found—	17.7	1679
	63.6	1578
S. Koch found for Hg vapour—	99.9	1589
	16.1	1558
	100	1558

The values of H should be identical for the same gas or vapour at all temperatures; the above agree quite as closely as any experimental determinations of η are likely to do.

Schumann gives—

	$\eta = \eta_0 \sqrt{1 + at(1 + \gamma t)^2}$	
For Air	$a = 0.003665$	and $\gamma = 0.000802$
„ CO ₂	$a = 0.003701$	„ $\gamma = 0.000899$
„ Esters	$a = 0.004$	„ $\gamma = 0.00164$
„ Benzol	$a = 0.004$	„ $\gamma = 0.00185$

Puluj between 3° and 30° C found—

for Air	$\eta = \eta_0(1 + 0.00265t) = \eta_0 T^{0.72}$
„ CO ₂	$\eta = \eta_0(1 + 0.003378t) = \eta_0 T^{0.92}$
„ H ₂	$\eta = \eta_0(1 + 0.002535t) = \eta_0 T^{0.60}$

S. Koch found for Hg vapour—

$$\eta = \eta_0(1 + at)^{1.60}$$

By means of these and similar formula values of η can be calculated for various temperatures with a very close approximation to the true values.

TABLE LXXc (3).—Variation in the Value of η with Change of Temperature.

Values of η_0 and of the constants in the formulæ :—

- (i.) $\eta_t = \eta_0(1 + \beta t)$ (O. E. Meyer and v. Obermayer.) (iv.) $\eta_t = \eta_0(1 + \alpha t)^n$ O. E. Meyer and v. Obermayer.
(ii.) $\eta_t = \eta_0(1 + \alpha t)^{\frac{1}{2}}$ (Sutherland.) (v.) $\eta_t = HT^{\frac{1}{2}}$ O. E. Meyer.
(iii.) $\eta_t = \eta_0 \sqrt{1 + \alpha t(1 + \gamma t)^2}$ (Schumann.) (vi.) $\eta_t = \eta_0 T^n$ Puluj.

TABLE LXXII. (3)—Variation of η with Temperature, etc.

$$Z = \text{Specific viscosity of substance} = \frac{\text{Absolute viscosity} \times 100}{\text{Viscosity of water at } 0^\circ}$$

$$\text{Graetz gives the formula } \eta_t = A \frac{\Theta - t}{t - S} \text{ or } Z_t = A_1 \frac{\Theta - t}{t - S}$$

where Θ = absolute boiling point, and
 S = absolute solidifying point of the liquid.

TABLE LXXII. (3a).

The following are the values of the constants, taking $\eta_0 = 0.0180456$ for water.
 A is the value of η midway between Θ and S .

Graetz found his formula inapplicable to the fatty alcohols and to ethylic ether, but Thorpe and Rodger, employing more recent data, found that for the ether the values—

$$A = 0·003338, \Theta = 194°·4, \text{ and } \Sigma = -227°·8$$

gave results that, on an average, differed less than 0·3 per cent. from their experimental results.

Thorpe and Rodger found that the equation runs given by $\eta = \frac{C}{(a + t)^n}$

$$\eta = \frac{C}{(a + t)^n}$$

gave very consistent results for some seventy-two liquids. The values of the constants as determined by them are given in the following table:—

Substance.	Formula.	Range of Temperature through which Equation applies.	Values of			Greatest Deviation of Calculated from Experimental Results.

TABLE LXXH. (3c).—Values of Constants in Slotte's Equation.

Slotte (*Beiblätter*, xvi. p. 182) gives the formula—

$$\eta_t = \frac{\eta_0}{(1 + bt)^n}$$

and the preceding is only a modification of this.

Slotte gave first the expression—

$$\eta_t = \frac{c}{a+t} - b, \text{ i.e. } \eta_t = \frac{c - ab - bt}{a+t} = b \cdot \frac{\left(\frac{c}{b} - a\right) - t}{a+t}$$

which is seen at once to be identical with the formula given by Graetz, when $A=b$, $\Theta = \frac{c}{b} - a$, and $\Sigma = -a$. He then found that the form $\eta_t = \eta_0 \frac{1 + \beta t}{(1 + at)^n}$ gave better results, and this equation he finally reduced to the form at the head of this paragraph.

Thorpe and Rodger give the following values for the constants:—

Substance.	Range.	η_0	b	n

The much older formula of Poiseuille,

$$\eta_t = \eta_0 / (1 + \alpha t + \beta t^2),$$

is somewhat more cumbersome, and in many cases does not give nearly so good approximations as Slotte's.

In the following table are given the values of the constants as calculated by Thorpe and Rodger. The ranges of temperature and the values of η_0 are to be taken as in the two last tables.

TABLE LXXII. (3d).—Values of α and β in Poiseuille's Equation.

TABLE LXXII. (3e).

Meyer finds that for a considerable number of liquids the simpler formula,

$$\eta_t = \eta_0 / (1 + at),$$

is enough for all practical purposes.

Substance.	η_0	a	Range.	Authority.
Water	0.0183	0.0369	0° to 33°·7	O. E. Meyer
"	01854	04635	42.01 " 89.4	Rosencranz

4.907 "	0230	0459	9.9 " 18.1	"
7.218 "	0253	0502	12.4 " 18.1	"
9.441 "	0296	0580	10.4 " 17.9	"

The preceding equations lend themselves readily to rapid interpolations. For us we must obtain an equation of the form given as No. 5 on page 5, *ante*:—

$$U_x = U_0 + x \Delta U_0 + \frac{x(x-1)}{1.2} \Delta^2 U_0 + \frac{x(x-1)(x-2)}{1.2.3} \Delta^3 U_0 + \frac{x(x-1)(x-2)(x-3)}{1.2.3.4} \Delta^4 U_0 + \text{etc.},$$

and from this we can readily interpolate terms to any extent by addition and subtraction.

The compiler, from the results obtained by various investigators, finds that the values give numbers agreeing very closely with the average values obtained by:—

$$\begin{aligned} U_0 &= 0.0180456 \\ \Delta U_0 &= -0.000537755634176 \\ \Delta^2 U_0 &= +0.000018241281536 \\ \Delta^3 U_0 &= -0.000000486030336 \\ \Delta^4 U_0 &= +0.00000006859776 \end{aligned}$$

TABLE LXXI.—Viscosity and Chemical Structure.

(1) In their monumental memoir Messrs Thorpe and Rodger strove to show the connection between the chemical structure and the viscosity of liquids. The following constants were calculated by them for the various elements, etc. :—

Putting $\eta l^2 = \eta \times \text{specific molecular area (in sq. cms.)} = \text{molecular viscosity.}$

$\eta l^3 = \eta \times \text{specific molecular volume (in c.cms.)} = \text{molecular viscosity work.}$

	At Boiling Point.		When $d\eta/dt = 0.000323.$		When $d\eta/dt = 0.000987.$

TABLE LXXK.—Effusion and Diffusion of Gases.

If A = area of a small aperture in envelope enclosing a mass of gas which, as a whole, is at rest;

n = average number of molecules in unit volume;

Ω = mean molecular speed;

then, number of molecules which in unit of time get to the orifice = $\frac{1}{4}nA\Omega$, and, if the envelope be thin, it is evident that the number of molecules passing through the orifice will be either equal to or directly proportional to the number that reach it; that is, directly proportional to Ω .

When any two gases are exerting the same pressure we must have—

$$\frac{1}{8}\pi\rho_1\Omega_1^2 = \frac{1}{8}\pi\rho_2\Omega_2^2$$

and if ρ_a = density of air, and s_1 and s_2 be the specific gravities of the gases referred to air thus becomes—

$$\frac{1}{8}\pi\rho_a s_1 \Omega_1^2 = \frac{1}{8}\pi\rho_a s_2 \Omega_2^2$$

$$\text{and } s_1 \Omega_1^2 = s_2 \Omega_2^2$$

$$\text{so } \Omega_1 : \Omega_2 = \sqrt{s_2} : \sqrt{s_1}.$$

That is the molecular speed, and consequently the number of molecules passing through a small orifice in a thin envelope every unit of time, varies inversely as the square root of the specific gravity: and the times of efflux of equal volumes will therefore vary directly as the square roots of the specific gravities of the gases. Taking air as the standard, Graham obtained the following comparative results—

Gas.	Square Root of Specific Gravity.	Time of Efflux of Unit Volume through	
		Drawn-out Glass Tube.	Perforated Brass Plate.
Air,	1.	1	1.
Hydrogen,	0.263	0.277 : 0.2637	0.276
Marsh gas,	0.745	0.756	: 0.753
Carbon monoxide, .	0.984	0.987	
Ethylene,	0.985		0.987
Nitrogen,	0.986	0.984	0.984 : 0.988
Oxygen,	1.051	1.053 : 1.0523	1.050 : 1.056
Nitrous oxide, . .	1.237	1.199	
Carbon dioxide, .	1.237	1.218 : 1.2483	1.197 : 1.209

Putting p for pressure per unit area exerted by a gas of the specific gravity s (air = 1) we have

$$s = 8p/\rho_a \Omega^2;$$

and thus from the rate of effusion one may calculate the specific gravity of a gas. Bunsen calculated the following values from the effusion speeds:—

Air	= 1.
Hydrogen	= 0.079
Electrolytic water-gas ($2H_2 + O_2$)	= 0.414
Oxygen	= 1.118
Carbon dioxide	= 1.535

Except in the case of hydrogen, these values agree within some 1 per cent. with those obtained by the usual methods.

The volumes which diffuse in equal times vary inversely as the square roots of the specific gravities. The following table gives Graham's results, and the values of s and $1/\sqrt{s}$ for comparison :—

Gas.	s .	$1/\sqrt{s}$.	Volumes diffused.
Air,	1.	1.	1.
Hydrogen,	0.0694	3.7959	3.83
Marsh gas,	0.555	1.3423	1.344
Ethylene,	0.972	1.0143	1.0191
Carbon monoxide,	0.972	1.0143	1.0149
Nitrogen,	0.972	1.0143	1.0143
Oxygen,	1.111	0.9487	0.9487
Hydrogen sulphide,	1.1805	0.9204	0.95
Nitrous oxide,	1.527	0.8092	0.82
Carbon dioxide,	1.527	0.8092	0.812
Sulphur dioxide,	2.222	0.6709	0.68

When one gas diffuses freely into another—not being separated from it by any sort of partition or diaphragm—then according to Loschmidt's observations—

Coefficient of diffusion $\propto T^2/P$ very nearly,

where T =absolute temperature and P =total pressure of gases= $P_1 + P_2$, the sum of the partial pressures of both.

O. E. Meyer gives the following :—

$$D = (\pi/8)(n_1\bar{\ell}_2\Omega_2 + n_2\bar{\ell}_1\Omega_1)/n,$$

where D =Coefficient of diffusion,

n_1, n_2 =Number of molecules of first and second gas respectively in 1 cm.³

$n = n_1 + n_2$.

$\bar{\ell}_1, \bar{\ell}_2$ =Free paths of the two kinds of molecules in the mixture.

$$\bar{\ell}_1 = \Omega_1/n_2\pi\sigma^2\sqrt{\Omega_1^2 + \Omega_2^2} \quad \text{and} \quad \bar{\ell}_2 = \Omega_2/n_1\pi\sigma^2\sqrt{\Omega_1^2 + \Omega_2^2}$$

where $\sigma = \frac{1}{2}(s_1 + s_2)$; s_1 and s_2 are the radii of the spheres of action of the two kinds of molecules.

Where we have only one gas, $\Omega_1 = \Omega_2$, $s_1 = s_2$, $n_1 = n_2 = n = \lambda^{-3}$ (λ = mean distance between neighbouring molecules) we have $\bar{\ell}_1 = \bar{\ell}_2 = \bar{L}$ and so—

$$\bar{L} = 1/n\pi s^2\sqrt{2} = \lambda^3/\pi s^2\sqrt{2}.$$

If we express λ in centimetres, then $n\lambda^3 = 1$ cm.³, and, putting m for the absolute mass of an individual molecule, we get—

$$nm = \rho \quad \text{and therefore} \quad \lambda^3 \rho = m.$$

We can approximate to the value of \bar{L} by means of the formula,

$$\bar{L} = 3\eta/\rho U;$$

LXXK₃.—Variation of D with Temperature.

$$D \propto (1 + \alpha t)^n$$

$$D_t = D_0(T_t/T_0)^n \cdot p/760,$$

where p is given in millimetres of ice-cold mercury. For the so-called permanent gases : approximates to 1·75, and for the more easily liquefiable gases to 2. For a range of temperature from about 18° C. to 62° C., v. Obermayer found the following values for n :—

Hydrogen	into oxygen,	$n = 1·755$
"	" carbon dioxide,	$n = 1·742$
Nitrogen	" oxygen,	$n = 1·792$
Oxygen	" carbon monoxide,	$n = 1·785$
Air	" carbon dioxide,	$n = 1·968$
Carbon dioxide	" nitrous oxide,	$n = 2·050$

In investigating the value of the coefficient of friction in a gas, we arrive at the expression—

$$\eta = mU/4\pi s^2 = \rho\lambda^3 U/4\pi s^2 \quad (5)$$

and this, in accordance with equation (2), gives us—

$$\eta = \frac{1}{3}\rho U \mathfrak{F}, \quad (6)$$

an expression exactly analogous to that for the pressure $p = \frac{1}{3}\rho U^2$.

Under a pressure of 760 mms. of mercury at 0° C. this, as already seen, works out to

$$\eta = 581.145575 \sqrt{\rho} \mathfrak{F}, \quad (7)$$

From equations (3) and (5) we get—

$$\eta = \rho \mathfrak{L}_1 U/2 \sqrt{2}, \quad (8)$$

And under the same conditions as in (7)—

$$\eta = 616.397966 \sqrt{\rho} \mathfrak{L}_1, \quad (9)$$

Equation (6) is equivalent to

$$\eta = 0.3618006 \rho \Omega \mathfrak{F}, \quad (10)$$

and (8) to

$$\eta = 0.3837475 \rho \Omega \mathfrak{L}_1, \quad (11)$$

O. E. Meyer gives—

$$\eta = \kappa mn \Omega L = \kappa \rho \Omega L, \quad (12)$$

and by means of rather complex formulæ, etc., he and Conrau have arrived at the value

$$\kappa = 0.30967, \quad (13)$$

(See O. E. Meyer's *Kinetic Theory of Gases*, English Edition.) The compiler gets a slightly lower value—about 0.309588—for κ , but the difference is quite insignificant, so we may accept

$$\eta = 0.30967 \rho \Omega L, \quad (14)$$

as a very close approximation to the truth.

For normal pressure this works out as—

$$\eta = 497.410277 \sqrt{\rho} L, \quad (15)$$

$$L = 0.0020104128 \eta / \sqrt{\rho}, \quad (15a)$$

Since

$$p = \pi \rho \Omega^2 / 8,$$

we may write (14) in the following form :—

$$\eta = 8p \times (0.30967 L / \pi \Omega), \quad (16)$$

or

$$\eta = 0.78857 p L / \Omega, \quad (17)$$

From the approximate values of the free paths we get :—
from (6) and (10),

$$\mathfrak{F} = 3\eta / \rho U = 2.76395 \eta / \rho \Omega, \quad (18)$$

from (8) and (11),

$$\mathfrak{L}_1 = 2 \sqrt{2} \eta / \rho U = 2.60588 \eta / \rho \Omega, \quad (19)$$

Putting \mathfrak{M}_H for the molecular weight of gas or vapour when $H_2 \equiv 2$,
 and \mathfrak{M}_O " " " " $O_2 \equiv 32$,
 we get at 0°C. —

$$\Omega = 239628 \cdot 1005 / \sqrt{\mathfrak{M}_H} = 240367 \cdot 3117 / \sqrt{\mathfrak{M}_O},$$

and therefore

$$\begin{aligned} L_0 &= 0 \cdot 29992 \eta / \sqrt{\mathfrak{M}_H} \text{ or very nearly } 0 \cdot 3 \eta / \sqrt{\mathfrak{M}_H}, \\ &= 0 \cdot 30085 \eta / \sqrt{\mathfrak{M}_O}, \end{aligned} \quad (19a)$$

Since s , the radius of the sphere of action of a molecule, must be equal to the diameter of the molecular sphere, we get—

Q = the sum of the diametral sections of all the molecular spheres contained in a unit volume $= n \times \pi s^2 / 4$, (20)

And, taking (3) as sufficiently near the truth for all purposes, we get—

$$n\lambda^3 = n\pi s^2 \sqrt{2}L = 1, \quad (20a)$$

and consequently

$$Q = 1/4 \sqrt{2}L = 0 \cdot 1767767/L, \quad (21)$$

With equal distribution of speeds, we get, in accordance with (2)—

$$Q = 3/16L, \quad (21a)$$

$$Q_0 = 0 \cdot 589413 \sqrt{\mathfrak{M}_H/\eta}, \quad (21b)$$

Putting

\mathfrak{v} = the space actually occupied by the n molecular spheres in a unit volume of gas $= \frac{1}{2} n \pi s^3$, (22)

and in accordance with (20a),

$$s = n\pi s^3 \sqrt{2}L = 6\mathfrak{v} \sqrt{2}L = 8 \cdot 485281 \mathfrak{v}L, \quad (22a)$$

Loschmidt has called \mathfrak{v} the *coefficient of condensation*. It denotes, according to our present notions, the smallest space into which it would be possible to compress the quantity of gas in a unit volume. If we compress a gas of density ρ until it condenses into a liquid of density d , we have then—

$$\rho/d = \mathfrak{v}, \quad (23)$$

For a large number of substances d and ρ have been experimentally ascertained; for all gases and vapours we can make close approximations to ρ from the following equations:—

$$\rho = \mathfrak{M}_H \times 0 \cdot 000044932 = \mathfrak{M}_O \times 0 \cdot 0000446560625, \quad (24)$$

and the values of s may be calculated directly from the values of L , \mathfrak{M} , and d , in accordance with the following expressions:—

$$s = 0 \cdot 0003812607L \mathfrak{M}_H/d = 0 \cdot 0003789192L \mathfrak{M}_O/d.$$

The correction made in (4), i.e., $2\pi s^3/3 = 4 \times \pi s^3/6 = b/n$ in Van der Waals's equation, so

$$b = 4\mathfrak{v} = 4n \times \pi s^3/6, \quad (25)$$

and we get approximately—

$$s = bL \times (3 \sqrt{2}/2), \quad (26)$$

If the value of b has been determined for a unit pressure, the last equation becomes—

$$s = pbL \times (3 \sqrt{2}/2), \quad (26a)$$

In the expression $\eta = 0 \cdot 30967 \rho L \Omega$ we have two magnitudes, η and Ω , which are independent of the pressure p , and as ρ practically varies directly as p , we have—

$$L \propto p^{-1}.$$

If we know the value of L under one pressure, we can calculate the values for all other pressures, and thus (26a) becomes available for the computation of the value of s under all conditions. This equation (26a) gives only roughly approximate values for s , and there are good reasons to believe that the multiplier 4 in (25) is considerably too high; indeed, the investigations of Clausius and Jäger point to the value $5/2$. So

$$b = 5h/2,$$

and

$$\begin{aligned} s &= (24 \sqrt{2}/10) bL = 6 \sqrt{2} hL, & (27) \\ 3\sqrt{2}/2 &= 2.12132034 \\ 24\sqrt{2}/10 &= 3.39411255 \end{aligned}$$

Dorn has applied the formula of Clausius to the calculation of s in some instances. Assuming the molecules to be spherical in shapes and perfect conductors of electricity, Clausius finds that

$$K = \text{the dielectric capacity} = (1 + 2v)/(1 - v),$$

and therefore

$$v = (K - 1)/(K + 2), \quad (27a)$$

Loschmidt's equation (22a) then becomes—

$$s = 6\sqrt{2}L(K - 1)/(K + 2) = 8.485281L(K - 1)/(K + 2), \quad (28)$$

According to Maxwell, if $\mu \equiv$ index of refraction of the gas, then—

$$v = (\mu^2 - 1)/(\mu^2 + 2), \quad (28a)$$

and

$$s = 6\sqrt{2}L(\mu^2 - 1)/(\mu^2 + 2), \quad (28b)$$

The values calculated according to (28) and (28a) will be much lower than those calculated according to (22a), (26), and (27).

Jäger, denoting the velocity U by c , h by l , and s by σ , employs the following approximate equations:—

$$\begin{aligned} b &= (1 - \frac{4}{3}n\pi\sigma^2)/n\pi\sigma^2 \\ l &= 3/4n\pi\sigma^2 \\ b &= 1/\sqrt{2}n\pi\sigma^2 \\ l &= 3\eta/\rho c \\ Q &= n\pi\sigma^2/4 = 3/16b \\ \sigma &= 8hl = 2bl \end{aligned}$$

We have no certain and definite knowledge of the relation between the temperature and the value of L ; at most L can only vary directly as the absolute temperature, and in general L changes more slowly than T . Winkelmann employs the formula:—

$$L_t = L_0 \sqrt{(1 + 0.004t)(1 + \alpha t)(1 + 0.00164t)^2}, \quad (29)$$

For substances which are gaseous at ordinary temperatures under atmospheric pressure, $\alpha \equiv 0.003665$ gives the best results; and for substances that are not gaseous, under such conditions $\alpha \equiv 0.00367$.

Putting $I \equiv$ mean duration of interval between two successive encounters of the same molecule, we get—

$$I = L/\Omega = \lambda^3/\sqrt{2}\pi s^2\Omega, \quad (30)$$

and putting $\Gamma \equiv 1/I =$ average number of encounters any one molecule takes part in in 1 sec., we get—

$$\Gamma = \sqrt{2}\pi s^2\Omega N = \Omega/L, \quad (31)$$

The temperatures marked (b) are the boiling points of the substances under a pressure of 760 mms. of ice-cold mercury. The values on all lines marked by an asterisk * are calculated according to the compiler's formulæ from values of η , etc., given in the preceding tables.

If the molecules of a liquid be considered as spheres, ρ/d will not correspond to $n\pi s^3/6$, but to $\{n\pi s^3/6\} \times 3\sqrt{2}/\pi$, i.e., to the smallest space into which n spheres of the diameter s can be compressed without distortion; so equation (22) becomes

$$\rho/d = \frac{1}{6}n\pi s^3 \times 3\sqrt{2}/\pi = \frac{1}{2}n s^3 \sqrt{2}, \quad (32)$$

or

$$v = \frac{1}{2}n\pi s^3 = (\rho/d) \times 0.74048049 = 0.74048049v, \quad (32A)$$

Thus we see that the values for v calculated from dielectric capacities or from the indices of refraction should be much smaller than the values of v deduced from the coefficients of condensation or from deviations from Boyle's law: in fact, the values actually calculated according to (27A) or (28A) differ from those of v to a far greater extent than one would expect from (32A).

From the values given on p. 426 for the quantity b , van der Waals has calculated the values of s for—

Air,	0.0,80
CO ₂ ,	63
H ₂ ,	40

As pointed out by Roth, b is not an absolute constant, but varies to a considerable extent with the temperature, and any values calculated from b can be but roughly approximate at best. As first approximations, the following values for v , calculated from the values ϕ in Table LXIX., may be of interest. The values in column A are calculated on the hypothesis that $b = 4\mathfrak{b} = (12 \sqrt{2}/\pi)v$, and those in column B by taking $b = (5/2)\mathfrak{b} = (5 \sqrt{2}/2\pi)v$.

TABLE LXXN.—Values of v calculated from Critical Volume.

Substance.	Values of v .		Substance.	Values of v .	
	A.	B.		A.	B.

Methane, .	108·3	0·416	1·8020	433	321	0658
Ethylene, .	169·5	0·571	2·0133	353	261	1102

The numbers in the third column have been calculated from the molecular weights, and the values of u and v at the various boiling points may therefore be considered as the lowest limits of possible values.

The exceedingly high values obtained by O. E. Meyer and others for s and other constants of hydrogen are evidently erroneous; u and v at boiling point would naturally be large, but so also would z , and from the physical properties of hydrogen we should expect s to be comparatively small.

TABLE LXXP.—Molecular Volumes, etc., of Liquids.

As far back as 1842, Kopp pointed out the dependence of the "Molecular Volume" on the chemical constitution, and since that time a great deal of work has been done, having for its object the determination of the laws which connect the molecular volumes of liquids with their chemical constitution. The comparing of the values for different liquids has been facilitated by calculating the molecular volumes at such temperatures as would give corresponding values for some important physical constant of all the liquids concerned, *e.g.*, by taking d = density of the liquid at its boiling point under atmospheric pressure, we get the values of M/d for all liquids when they have the same vapour pressure. Possibly more accordant results would be obtained if we could find d when the viscosity was the same for all the substances concerned.

Taking the weight of one atom of hydrogen as our unit for M , then the space occupied at 4° C. by this weight of water will be the unit in the values of the molecular volumes; or if M be considered as the "Mol" or gramme molecule, then the molecular volumes will be expressed in centimetre cubes.

The liquids experimented with have been mostly organic compounds, as the paucity of the elements entering into the formation of these has greatly facilitated comparisons.

From the results obtained by Kopp and subsequent investigators, Lothar Meyer concluded that "The atomic volumes of elements (at least several of them) in their liquid combinations are proportional to the spaces occupied by their atoms in the gaseous state."

H. Kopp found that the addition of the group CH_2 to an organic compound corresponded to an increment of 22 in the molecular volume; thus

	Δ	
Formic acid, . $\text{CH}_2\text{O}_2 \equiv$	41.8	
Acetic acid, . $\text{C}_2\text{H}_4\text{O}_2 \equiv$	63.5	21.7
Propionic acid, $\text{C}_3\text{H}_6\text{O}_2 \equiv$	85.4	21.9
Butyric acid, . $\text{C}_4\text{H}_8\text{O}_2 \equiv$	107.8	22.4
		} mean 22

Also that the atomic volume of carbon is double that of hydrogen; for

Octane, . . .	$\text{C}_8\text{H}_{18} \equiv$	184.6
Cymol, . . .	$\text{C}_{10}\text{H}_{14} \equiv$	184.6

and therefore

and in this way he inferred that

$$\text{C} \equiv 11, \text{ and } \text{H} \equiv 5.5.$$

The following values for the atomic volumes in liquids at the boiling points thereof have been adopted by various investigators:—

	Kopp.	Loschmidt.	Lossen.	Thorpe.
Hydrogen,	5.5	3.5	5.05; 5.225	
Carbon,	11	14	10.1; 10.45	
Nitrogen (in ammonias),	2.3		7	
„ (in CN group),	17	13		
„ (in nitro-derivatives),	8.6			
Oxygen (hydroxylic),	7.8	11	10.1; 10.45	
„ (carboxylic),	12.2	(O ₂)21		
Fluorine,				9.2
Silicon,	32			30
Phosphorus (Triad),	25.4		25.9	25.3
„ (Pentad),			19.3	
Sulphur (C-S),	22.6		23.5	22.6
„ (C=S),	28.6	26		28.6
Chlorine,	22.8	21.8	22.8	22.7
Titanium,	35			33.7
Vanadium,				30.4
Chromium,				24.5
Zinc,				40.3
Arsenic,	26			26.3
Bromine (Br ₂),				53.6
„ (Br),	27.8		29.1	28.1
Tin,	40			
Antimony,	33			28.6
Iodine,	37.5		39.6	36
CN,	28	28	30	
NO ₂ ,	33		32.6	32
CH ₂ ,	22		20.9	

Thus for a compound of the formula $C_xH_yO_zO_w$, where O denotes hydroxylic oxygen or oxygen joined by one bond only to one carbon atom, and O denotes carboxylic oxygen, i.e., oxygen doubly linked to one carbon atom, we get, according to Kopp—

$$V = 11x + 5.5y + 7.8z + 12.2w.$$

Lossen has employed formulæ, etc., that differ considerably from those of Kopp; thus for the acids and esters $C_nH_{2n}O_2$ he finds that

$$C_2H_4O_2 = 62.7,$$

and employs, for the general calculation of molecular volumes, the equation

$$\begin{aligned} \text{Molecular volume of } C_nH_{2n}O_2 \\ &= 62.7 + (n-2)20.9 + \left(\frac{1}{2} + \frac{2}{2} + \frac{3}{2} + \dots + \frac{n-3}{2}\right) \\ &= 62.7 + (n-2)20.9 + \frac{1}{4}(n-2)^2. \end{aligned}$$

He modifies this expression in several ways so as to make it applicable to different classes of compounds; thus for saturated compounds:—

$$\begin{aligned}\text{Molecular volume of } C_nH_mO_p \\ &= 10.45n + 5.225m + 10.45p + \frac{1}{4}(n-2)^2 \\ &= 10.16(n+p) + 5.08m + 0.23n^2.\end{aligned}$$

For unsaturated compounds:—

$$\begin{aligned}\text{Molecular volume of } C_nH_mO_p(\mu) \\ &= 10.45(n+p) + 5.225m + \frac{1}{4}(n-2)^2 + 1.5\mu,\end{aligned}$$

where μ represents the number of hydrogen atoms required to convert the formula into that of a saturated compound. For alcohols this formula is best written as follows:—

$$\begin{aligned}\text{Molecular volume of } C_nH_mO_p(\mu) \\ &= 10.1(n+p) + 5.05m + \frac{1}{4}(n-2)^2 + 1.35\mu.\end{aligned}$$

A still more general form of the expression is

$$\begin{aligned}\text{Molecular volume of } C_nH_mO_p(\mu) \\ &= (10.24 \pm 0.5x)(n+p) + (5.12 \pm 0.25x)m + \frac{1}{4}(n-2)^2 + 1.4\mu,\end{aligned}$$

where x is a number varying between 0 and 1 for various homologous series, but remaining constant for members of the same series.

Traube considers that the so-called "Atomic Volumes" are made up of two distinct portions—(a) the space actually filled by the material nucleus or atom, and (b) the space in which this nucleus performs its oscillatory or other intramolecular movements; a probably remains constant under all conditions, but we should expect b to vary considerably with the nature and intensity of atomic movements. This investigator has found that the sum $a+b$ does vary considerably for various elements, *e.g.*, for N in several primary amines $a+b=1.5$, but in tri-isobutyl amine $a+b$ for N=13. The molecular volume M_v he considers to be made up of the sum of the atomic volumes and a magnitude which he terms the "Co-volume," varying with the temperature.

$$\text{Co-volume (of liquid or solid) at } t^\circ \text{ C.} = 24.5(1 + \alpha t),$$

where α = coefficient of expansion for gases. At 15° C. the value becomes 25.9 practically.

Traube has given us the following values for the sum of $a+b$ at or near 15° C. :—

H	≡ 3.1.
C	≡ 9.9.
N	≡ 1.5 in primary amines.
N	≡ 10.7 Pentavalent.
N	≡ 8.5 to 10.7 in nitro-derivatives.
N	≡ 13 (about) in some tertiary amines.
O	≡ 5.5 Doubly linked to carbon, either one or two C atoms.
O	≡ 2.3 Extra-radicle.
O	≡ 0.4 in OH in O=C—O—H, etc.
P	≡ 17.0 Trivalent.
P	≡ 28.5 Pentavalent.
S	≡ 15.5 Sulpho-hydryl, sulpho-carbonyl.
S	≡ 10 to 11.5 united to oxygen.
Cl	≡ 13.2.
Br	≡ 17.7.
I	≡ 21.4.
CH ₃	≡ 16.1; 15.97 @ 0° ; 17.13 @ 100° .
CN	≡ 13.2.

Traube's formula for the molecular volume at 15° C., is

$$M/d_{15} = \text{Sum of atomic volumes} + 25.9.$$

On liquefaction we know that many substances undergo polymerisation, and if we deduce M from vapour density, etc., we have to remember that

$$M = \text{molecular weight of liquid} = nM,$$

and

$$M/d_{15} = \{n \times \text{sum of atomic volumes in vapour mol.}\} + 25.9.$$

or

$$M/d_{15} = \Sigma (\text{atomic volumes}) + 25.9/n.$$

From this we can determine the "Association Factor" n , *i.e.*, the mean number of gaseous particles that combine to form one liquid particle.

Traube's values for n are :—

For Acetic acid,	1.40
Ethyl alcohol,	1.51
Methyl alcohol,	1.66
Formic acid,	1.67
Glycerine,	1.75
Glycol,	2.00
Water,	above 3

LXXI.—Capillarity and Surface Tension.

Poisson found that, when a disc of radius R is pulled vertically upwards from the surface of a liquid,—

$$p = \pi R^2 h s,$$

where

p = force exerted at the moment of separation,

h = length of the raised column of liquid,

s = density of liquid,

and

$$h = a\sqrt{2} - a^2/3R,$$

where a is a constant depending on the nature of the liquid. If R is very large then, practically,—

$$h = a\sqrt{2},$$

where a^2 = specific cohesion of the liquid.

For any given liquid in contact with a given solid with a definite intimation of contact—this intimation to some extent depending upon the condition as well as upon the nature of the solid—there is for every specified temperature a definite angle of contact between the liquid and solid surfaces, which is practically independent of the direction of these surfaces as regards the vertical. This angle we denote by θ and sometimes by ϕ .

Every liquid behaves as if the thin film forming its exterior surface was in a state of tension, because the molecules which form the surface of the liquid are subject to attraction (or repulsion) by other liquid molecules only on one side. This tension must be expressed in units of force per linear unit, and is usually denoted by α ; it is identical with Laplace's $H/2$.

If a solid wall or plate be dipped perpendicularly into a liquid the surface of the liquid in the immediate vicinity of the wall will be distorted by the elevation or depression of a certain mass of the liquid. This distortion will result from the force α acting throughout l , the length of the wall, at an angle θ with the vertical, so that the mass of liquid displaced will be,—

$$l\alpha \cos \theta.$$

If θ be less than 90° the cosine will be positive and the liquid will be raised, while if $\theta > 90^\circ$ the cosine will be negative and the effect will be a depression. If the wall be circular with radius r we get,—

$$l = 2\pi r,$$

and the weight of liquid displaced becomes,—

$$2\pi r\alpha \cos \theta.$$

Putting h for the length of the displaced column of liquid, and supposing the meniscus to be hemispherical, we get for its volume,—

$$\pi r^2(h \pm r/3),$$

and if σ represents the density of the liquid, its mass will be,—

$$\pi r^2\sigma(h \pm r/3),$$

and therefore,—

$$2\pi r\alpha \cos \theta = \pi r^2\sigma(h \pm r/3) = \pi r^2h\sigma(1 \pm r/3h).$$

If the meniscus be a semi-ellipsoid of revolution:—

$$2\pi r\alpha \cos \theta = \pi r^2h\sigma(1 \pm r/3h - r^2/9h^2 \pm 2r^3/27h^3U).$$

As r is generally very small as compared with $3h$ we may, in most cases, take—

$$2\pi r a \cos \vartheta = \pi r^2 h \sigma,$$

and,
$$h = 2a \cos \vartheta / r \sigma; \cos \vartheta = h r \sigma / 2a.$$

Now for the same liquid at a constant temperature a , σ , and ϑ remain constant, so—

$$h \propto 1/r,$$

which expresses Jurin's law.

When $r = 1$ we get
$$h = 2a \cos \vartheta / \sigma,$$

and if the liquid wets the tube $\vartheta = 0$ and $\cos \vartheta = 1$, so—

$$h = 2a/\sigma = a^2 = \text{specific cohesion.}$$

Between two parallel plates separated by a distance d ,—

$$h = 2a \cos \vartheta / d \sigma.$$

Putting $\beta \equiv$ adhesion constant of the liquid and solid, we get

$$\cos \vartheta = \beta / a,$$

and the expression for the height to which a liquid will be displaced in a tube of radius r becomes

$$h = 2\beta / r \sigma.$$

When the liquid thoroughly wets the solid we have, as seen above,

$$\cos \vartheta = 1,$$

and therefore,

$$a = \beta.$$

As $\beta = a \cos \vartheta$, it is evident that β can never exceed a , but in every case, except where $\vartheta = 0$, the numerical value of β will be smaller than that of a .

The following are the symbols generally employed and their significations:—

Surface tension, or capillarity constant, $H/2$ (Laplace) $= a = a^2 \sigma$ (Gauss): in the tables generally given in mgms. per mm. length; ag gives surface energy per cm.² in ergs; or surface tension per cm. in dynes.

Specific cohesion, $a^2 = H/\sigma$ (Laplace) $= 2a^2$ (Gauss) $= 2a/\sigma$: denotes in mms. the extent to which a liquid is raised or depressed in a tube whose radius is 1 mm.

Adhesion constant, $\beta = a \cos \vartheta$: expressed in terms of same units as a .

Contact angle, $\vartheta = \cos^{-1} (\beta/a)$.

When a large drop of liquid rests on a horizontal smooth surface, or a bubble of air (or other gas) is formed against such a surface, the drop or bubble will assume, on the side furthest from the plane, the figure of a solid of revolution: and if

H = distance between plane and the point in the surface of the drop or bubble furthest from it = maximum thickness of drop or bubble;

h = distance between the point referred to above and the maximum horizontal section of drop or bubble = distance between highest or lowest point and the plane meeting the surface of the drop or bubble at every point where the tangent to such surface is vertical;

then, taking a , a^2 , β , and σ with the same significations as before, we get—

$$a = \sigma h^2 / 2 \text{ in gravitation units} = g \sigma h^2 / 2 \text{ in absolute units};$$

$$\text{also} \quad a = \sigma H^2 (2 + 2 \cos \vartheta) \quad ,, \quad = g \sigma H^2 / (2 + 2 \cos \vartheta) \quad ,,$$

whence,—

$$h^2 = H^2 / (1 + \cos \theta),$$

$$\therefore \cos \theta = (H^2 - h^2) / h^2.$$

Since

$$a = g\sigma H^2 / (2 + 2 \cos \theta) = g\sigma H^2 / 4 \cos^2 \frac{\theta}{2}$$

$$H^2 = 4a \cos^2 \frac{\theta}{2} / g\sigma;$$

that is, when the surface of a drop or bubble ceases to be a portion of an exact spherical surface, the maximum thickness of the drop or bubble is quite independent of its magnitude.

$$\cos \frac{\theta}{2} = H / h\sqrt{2}.$$

Eötvös finds the value of a (square root of the "specific cohesion") by measuring the angle between the surface-normal and the vertical at two points of different elevation on the curved surface of a liquid. If ϕ denote this angle and Z the height of the point above the plane of no curvature, we get for any point

$$Z = a\sqrt{2} \sin \frac{\phi}{2}.$$

Denoting by $Z_1, \phi_1; Z_2, \phi_2$, the values as determined for two points such as referred to above, we have

$$a = \frac{Z_2 - Z_1}{\sqrt{2} \left(\sin \frac{\phi_2}{2} - \sin \frac{\phi_1}{2} \right)}.$$

In the case of a drop falling from the horizontal end of a cylindrical tube of radius r , supposing that at the instant of separation the section of the drop at the end of the tube is circular with radius r , we have the surface tension $2\pi r a$ round the circumference just in equilibrium with the total downward force, *i.e.* the weight of the drop + excess of pressure of liquid inside over the atmospheric pressure. Put w = weight of drop

$$2\pi r a = w + \pi r a \text{ or } \pi r a = w.$$

But this formula is not quite accurate, as the form of the drop at the instant of separation is never exactly that assumed. Lord Rayleigh finds that practically

$$w = 3.8ra$$

is much nearer the truth than

$$w = 3.14159ra.$$

The equation generally used,

$$w = 2\pi r a,$$

is entirely wrong, as it ignores the change of pressure inside the drop caused by the curvature of its surface.

For the same tube the number of drops is supposed to be proportional to $2a/\sigma$, but Duclaux found that with a pipette which at 20° C. gave 100 drops for 5 c. cms. of water the following corrections had to be made:—

Number of drops up to	140	150	160	170	180	190	200	210	220	230	240	250	260
Deduct	0	1	2	2.5	3	4	5	6	7	8.5	10	11	12

and one more for every 20 drops above 260.

When a series of waves are propagated on the surface of a liquid the surface tension has the effect of increasing the pressure at the crests of the waves and diminishing it in the troughs, so—

$$f = g + 4\pi^2 a / \lambda^2 \sigma \quad (b)$$

and therefore

$$\begin{aligned} V^2 &= n^2 \lambda^2 = (g + 4\pi^2 a / \lambda^2 \sigma) (\lambda / 2\pi) \tanh \frac{2\pi h}{\lambda} \\ &= (g\lambda / 2\pi + 2\pi a / \lambda \sigma) \tanh \frac{2\pi h}{\lambda} \end{aligned} \quad (c)$$

$$\therefore a = \sigma \left(\coth \frac{2\pi h}{\lambda} \cdot n^2 \lambda^3 / 2\pi - g\lambda^2 / 4\pi^2 \right) \quad (d)$$

$$\text{Now } \coth \chi = \cosh \chi / \sinh \chi = 1 / \tanh \chi = \frac{\frac{1}{2}(e^\chi + e^{-\chi})}{\frac{1}{2}(e^\chi - e^{-\chi})} = \frac{1 + e^{-2\chi}}{1 - e^{-2\chi}};$$

so—

$$a = \sigma \left(\frac{1 + e^{-\frac{4\pi h}{\lambda}}}{1 - e^{-\frac{4\pi h}{\lambda}}} \cdot \frac{n^2 \lambda^3}{2\pi} - \frac{g\lambda^2}{4\pi^2} \right) = \sigma \left\{ \left(1 + 2e^{-\frac{4\pi h}{\lambda}} \right) \cdot n^2 \lambda^3 / 2\pi - g\lambda^2 / 4\pi^2 \right\} \quad (d_1)$$

unless h be quite insignificant as compared with λ . When $\lambda = 0.5$ cm. and $h = 1.1$ cm. (the limiting values used by Dorsey in his investigations), we get $4\pi h / \lambda = 27.6 +$; so $e^{-\frac{4\pi h}{\lambda}}$ is less than $1 / (9.69 \times 10^n)$, and consequently $\coth \frac{2\pi h}{\lambda}$ differs from unity by less than $1 / (4.8 \times 10^n)$; when $\lambda = 0.5$ and $h = 0.4$ the difference from unity is only about $1/2300$, and when h is as small as 0.3 the deviation is only $1/1900$; so we may, in all cases likely to occur in using the method of ripples, take $\coth \frac{2\pi h}{\lambda} = 1 = \tanh \frac{2\pi h}{\lambda}$, and equation (c) becomes

$$V^2 = n^2 \lambda^2 = g\lambda / 2\pi + 2\pi a / \lambda \sigma \quad (e)$$

$$\therefore V = \sqrt{(\lambda / 2\pi)(g + 4\pi^2 a / \lambda^2 \sigma)} \quad (e_1)$$

This will be a minimum when $g = 4\pi^2 a / \lambda^2 \sigma$, which gives for λ_m (wave-length corresponding to minimum velocity)

$$\lambda_m = 2\pi \sqrt{a / g \sigma} \quad (f)$$

and the minimum velocity will be

$$\sqrt{2} (ag / \sigma)^{\frac{1}{4}} \quad (g)$$

Thus for water at 0° C. we have given $a = 77.74$, and by equations (f) and (g) we find that

$$\lambda_m = 1.78 \text{ cm.}$$

and the minimum velocity = 23.5 cm./sec.

In other words, no wave can travel on the surface of ice-cold water with a smaller velocity than 23.5 centimetres per second. Acting on Lord Kelvin's suggestion, the term "waves" is now confined to such as have wave-lengths not less than λ_m , and the term "ripples" (Germ. *Kräuselungen*) to those with wave-lengths less than λ_m .

When the effect of surface tension is negligible we have what may be termed pure "gravitation waves," and for these the term involving a vanishes and equation (e) becomes

$$V^2 = (g\lambda / 2\pi) \tanh \frac{2\pi h}{\lambda} \quad (h)$$

and when λ is large compared with h

$$V = \sqrt{gh} \quad (i)$$

when λ is small in comparison with h

$$V = \sqrt{g\lambda/2\pi} \quad (j)$$

For waves, whose lengths from crest to crest exceeds λ_m , the principal force concerned in their motion is gravitation; for ripples the principal force concerned is surface tension. For ripples, as we have already seen, equation (d₁) may be written

$$\alpha = \sigma(n^2\lambda^3/2\pi - g\lambda^2/4\pi^2) \quad (k)$$

For the production of ripples a tuning fork is generally employed, and if t = time of vibration of fork, then $t = n^{-1}$ and

$$\alpha = \sigma(\lambda^3/2\pi t^2 - g\lambda^2/4\pi^2) = (\sigma/2\pi)(\lambda^3/t^2 - g\lambda^2/2\pi) \quad (l)$$

For convenience in calculation we may write equation (k) as follows:—

$$\alpha = (\sigma n^2 \lambda^3 / 2\pi) (1 - g/2\pi n^2 \lambda) \quad (m)$$

or near enough for all practical purposes.

$$\alpha = 0.15915 \sigma n^2 \lambda^3 (1 - 156/n^2 \lambda) \quad (m_1)$$

In actual working the second term within the bracket will be generally small, but not always negligible; three figures of the initial coefficient will be sufficient, except in calculating the results of very careful experiments with very accurate apparatus.

For a liquid of infinite depth in contact with air (or other gas) Lamb gives—

$$V^2 = \frac{\sigma - \rho}{\sigma + \rho} \cdot \frac{g\lambda}{2\pi} + \frac{2\pi\alpha}{(\sigma + \rho)\lambda}$$

$$\alpha = (\sigma + \rho) \left\{ \frac{n^2 \lambda^3}{2\pi} - \frac{\sigma - \rho}{\sigma + \rho} \cdot \frac{g\lambda^2}{4\pi^2} \right\}$$

where ρ = density of air (or other gas).

Lenard determined the values of α by observing the oscillations of large spherical drops, relieved from the effects of gravitation by being suspended in a non-mixing liquid of practically identical density. Putting t for time of gravest vibration about the spherical form after distortion, r for radius of drop, he found

$$t = (\pi / \sqrt{2}) \sqrt{\sigma r^3 / \alpha} = 2.22144 \sqrt{\sigma r^3 / \alpha} \quad (n)$$

so

$$\alpha = \frac{\pi^2 \sigma r^3}{2t^2} = 4.9348 \sigma r^3 / t^2 \quad (n_1)$$

At 4° C. the period of a spherical drop of water with radius of 2.5 cms., when oscillating about the spherical form under the action of surface tension alone, is almost exactly 1 second.

For a spherical cavity of radius r with one free surface, such as an air bubble in a liquid, the excess of pressure inside the cavity over that outside is—

$$2\alpha/r,$$

and for a bubble with two free surfaces and very thin envelope, such as a soap bubble floating in air, the difference is—

$$4\alpha/r.$$

Jäger based his experimental method on this difference of pressure—he estimated the least pressure that would force bubbles of air from the narrow orifice of a capillary tube dipping beneath the surface of a liquid; the method is better adapted for comparative than for absolute measurements.

Influence of Temperature on Surface Tension, etc.

For all liquids there is a *diminution* of surface tension with an *increase* in the temperature, but the law connecting the two cannot be said to be thoroughly understood. The following empirical equation is frequently employed to denote the relation between surface tension and temperature—

$$\alpha_t = \alpha_0(1 - \mu t + \xi t^2).$$

Constant ξ has frequently the value 0, so that—

$$\alpha_t = \alpha_0(1 - \mu t).$$

For water and other liquids various values for the constants in these equations are given in Table LXXI_F.

Knipp gives the following proportional numbers for the surface tension of water up to its critical temperature:—

	Numbers Proportional to Surface Tension.	t° .	Numbers Proportional to Surface Tension.	t° .	Numbers Proportional to Surface Tension.	t° .	Numbers Proportional to Surface Tension.
C.	44.2	100° C.	31.6	200° C.	19.3	300° C.	7.2
	43.2	110	30.4	210	18.2	310	6.2
	41.7	120	29.1	220	17.	320	5.5
	40.5	130	27.9	230	15.7	330	4.7
	39.1	140	26.7	240	14.5	335	4.4
	37.8	150	25.5	250	13.2	340	4.1
	36.6	160	24.1	260	12.1	345	3.9
	35.4	170	23.	270	10.9	350	3.4
	34.1	180	21.9	280	9.7	352.5	3.
	32.9	190	20.6	290	8.5	355	2.1
						357.5	1.

Thus if the surface tension be 77.74 at 0° we get—

$$\alpha_{100} = \frac{77.74}{44.2} \times 31.6 = 55.58 \text{ very nearly,}$$

which does not agree at all with the value calculated from Knipp's formula—

$$\alpha_{100} = \alpha_0\{1 - (100 \times 0.00191)\} = 62.89,$$

with the value obtained by the compiler

$$59.28.$$

At the critical temperature, as there can be no separating surface between a liquid and its vapour, it was supposed that the surface tension would become *nil*, so that

$$\alpha_c = \alpha_0(1 - \mu c) = 0$$

and $\mu c = 1.$

None of the formulæ of this form given for water will give anything near the experimental value for ϑ ; the lowest value for μ gives

$$\bullet \quad \vartheta = 556^{\circ} \text{ C.},$$

and the highest—

$$\vartheta = 435^{\circ} \text{ C.}$$

Of the formulæ of the form—

$$a_{\vartheta} = a_0(1 - \mu\vartheta + \xi\vartheta^2)$$

Wolff and Weinberg's will give no value for ϑ , but the one adopted by the compiler from surface tension results merely, and without any reference at first to the critical temperature, gives—

$$\vartheta = 343^{\circ} \text{ C.},$$

which is most probably within some twenty degrees of the true value: a pretty close approximation starting with a somewhat erroneous hypothesis.

TABLE LXXIF.—Relations between Surface Tension, etc., and Temperature. (From R. Schiff's Determinations.)

t° = boiling temperature under pressure B.
 B = pressure under which the boiling temperature was observed.
 σ = density of liquid at its boiling point under pressure B.
 M/σ = molecular weight divided by the density = molecular volume at the boiling point.
 τ° = temperature between which and t° the capillarity constants were determined.
 a° = specific cohesion at 0° (calculated).

* All results marked with an asterisk are from Schiff's later researches.

Capillarity Constants of Solutions.

Buliginsky gave the following empirical formula for the surface tension of aqueous solutions :—

$$\alpha_s = \alpha_w(p + kq),$$

where—

α_s = surface tension of solution.

α_w = " " " " pure water.

p = weight of water in one gramme of the solution.

q = " " " " substance

k = a constant depending on the nature of the substance in solution.

For KNO_3 at 15°C . he found

$$k = 1.1628 \text{ nearly,}$$

and for NH_4Cl at about 16°C .,

$$k = 1.3895.$$

Quincke gives for aqueous solutions :—

$$\alpha_s = \alpha_w + ky; \text{ i.e. } \alpha_s = 7.35 + ky,$$

where y = number of "salt-equivalents" (he really employs double the chemical equivalents) to every 100 molecules of water,

k = a constant as before.

For chlorides he finds, employing capillary tubes,

$$k = 0.1783;$$

but by the air-bubble method he gets

$$\alpha_s = 8.30 + 0.1870 y.$$

These equations give moderate approximations for solutions of chlorides and also for solutions of magnesium sulphate, potassium carbonate and sodium carbonate, but they break down completely for those of potassium sulphate, sodium sulphate, zinc sulphate, copper sulphate and sugar.

Dorsey gives an equation of the form,—

$$\alpha_s = \alpha_w + kc,$$

where c = gramme equivalents per litre of the solution. The values of k for a few substances, as calculated from the work of various investigators, may be thus tabulated :—

k for	Volkmann.	Quincke.	Sentis.	Rother.	Dorsey.
NaCl , . .	1.59	1.57	1.57	1.38	1.53
KCl , . .	1.41	1.57	1.41	1.47	1.71
$\frac{1}{2} \text{K}_2\text{CO}_3$, . .	1.78	1.57	1.77
$\frac{1}{2} \text{Na}_2\text{CO}_3$, . .	0.987	1.57	2.00
$\frac{1}{2} \text{ZnSO}_4$,	1.78	...	1.86

Sentis gives the following equation :—

$$\alpha_s \sqrt[3]{v/u} = (100-n)\alpha_w/100 + \phi$$

where u = volume of 100 molecules of water,

v = volume of the mixture of $(100-n)$ molecules of water with n molecules of the anhydrous salt.

ϕ = A constant, which, between 0° and 30° , appears to be independent of the temperature.

This investigator found that ϕ is sensibly constant for all strengths up to saturation for salts that have a considerable negative heat of solution, but it increases with the concentration for those salts which, when rendered anhydrous, dissolve with an evolution of heat. The limiting value of ϕ/n he finds to be 1.66 dynes per cm. for salts with two radicles and $(3/2)$ times this, *i.e.* 2.49 dynes, for salts with three radicles.

Volkmann gives the following values for k in Quincke's equation :—

BaCl ₂ ,	0.174	K ₂ SO ₄	0.153
SrCl ₂ ,	187	Na ₂ SO ₄	152
CaCl ₂ ,	204	MgSO ₄	133
MgCl ₂ ,	197	K ₂ N ₂ O ₆	105
K ₂ Cl ₂ ,	159	Na ₂ N ₂ O ₆	111
Na ₂ Cl ₂ ,	181	K ₂ CO ₃	190
(NH ₄) ₂ Cl ₂ ,	130	Na ₂ CO ₃	112

And Rother gives the following :—

For NaCl,	$\alpha_s = 7.357 + 0.1566y$
„ KCl,	$7.357 + 0.1666y$
„ Na ₂ SO ₄ ,	$7.357 + 0.1382y$
„ K ₂ SO ₄ ,	$7.357 + 0.1595y$

Valson (about 1870) concluded that the surface tension of salt solutions was a merely additive property, and that the capillary action of each positive and each negative radicle is constant and quite independent of that which may be combined with such radicle. The following are the numbers given by Valson for tubes 0.5 mm. diameter, in which he found a normal solution of ammonium chloride to ascend 60.9 mms. at 15° C.

TABLE LXXI_G.—Capillary Moduli.

Radicle.	Equivalent.	Modulus.	Radicle.	Equivalent.	Modulus.
Ammonium,	18	0.0 mm.	Silver,	108	5.5 mm.
Lithium,	7	0.05	Lead,	104	5.9
Sodium,	23	1.2	Thallium,	203	7.9
Magnesium,	12	1.4	Cl in chlorides,	35.5	0.0
Calcium,	20	1.4	CO ₃ in carbonates,	30	0.5
Potassium,	39	1.5	NO ₃ in nitrates,	62	1.0
Manganese,	27.5	2.5	C ₂ O ₅ in bicarbonates,	52	1.1
Iron,	28	2.5	SO ₄ in sulphates,	48	1.2
Zinc,	32.5	2.7	SO ₃ in sulphites,	40	1.3
Copper,	32	2.9	S ₂ O ₃ in thiosulphates,	56	1.4
Strontium,	44	2.9	Br in bromides,	80	2.1
Barium,	69	3.9	I in iodides,	127	3.9
Cadmium,	56	4.3			

Employing these moduli, we find that the ascent of barium chloride solution should be $60.9 - 3.9 = 57$ mms., which agrees with the value obtained experimentally; for ammonium sulphate $H = 60.9 - 1.2 = 59.7$ mms., and the value obtained by actual experiment is 59.9; for cadmium sulphate we get $H = 60.9 - (4.3 + 1.2) = 55.4$, while experiment gave 56.2 mms. The symbols, equivalents, etc., are printed as given by Valson.

At a later period, working with tubes of the same dimensions, Valson found that for normal solutions the "capillary contents" (*i.e.* height multiplied by the density) is practically constant for many, if not for all, salts; the product DH seems to tend to a limiting value of about 61.7. Of 42 salt solutions examined by this investigator, only three gave lower values than 61.4, and only a similar number exceeded 62.

TABLE LXXI_g.

	Equivalent	Chloride.			Bromide.			Iodide.			Sulphate.			Nitrate.		
		H.	D.	DH.	H.	D.	DH.	H.	D.	DH.	H.	D.	DH.	H.	D.	DH.

Cadmium, .	56	57.2	1.078	61.8	55.0	1.113	61.2	53.2	1.142	60.7	56.0	1.098	61.5	56.2	1.091	61.7
Barium, .	69	57.0	1.088	62.0										56.0	1.101	61.6
Lead, .	104													54.1	1.133	61.6
Silver, .	108													54.5	1.133	61.7

H = Height to which the liquid ascends in capillary tubes 0.5 mm. diameter at 15° C.

D = Density of the normal solution at 15° C.

The preceding numbers also agree very closely with the following expression,—

$$H = 118.5 - 56.8 D,$$

so that in exchanging one normal solution for another, the alteration in the length of the capillary column is inversely proportional to the change in density.

Röntgen and Schneider, from their investigations on surface tensions and compressibility, calculated the surface tensions of solutions of the iodides, nitrates, bromides, chlorides, hydroxides, sulphates and carbonates of hydrogen, ammonium, lithium, sodium and potassium; they expressed the results in arbitrary units (*hd*), and from these the values of α in mgrms./mm. have been computed.

The values of α in milligrammes per millimetre correspond to a temperature of 15° C.

Jäger found the following values, in dynes per cm.² at 13°·5 C., for the various solutions :—

Water,		73·035
Solution of NaCl,	19·9 per cent.,	77·479
" "	10·4 "	75·179
" KCl,	20·5 "	75·423
" "	10·3 "	74·513
" NH ₄ Cl,	22·4 "	78·306
" "	11·3 "	75·668
" MgCl ₂ ,	19·6 "	77·994
" "	12·3 "	75·654
" NaNO ₃ ,	24·6 "	74·942
" "	12·4 "	74·355
" Na ₂ CO ₃ ,	10·3 "	74·255
" sugar,	35·2 "	73·511
" "	25·2 "	73·346

These values correspond very closely to the following empirical expressions, where p denotes the percentage of salt in the solutions :—

$$\begin{aligned}
 \alpha \text{ for NaCl} &= a_w(1 + 0\cdot0_225653p + 0\cdot0_424747p^2) \\
 \text{" " KCl} &= a_w(1 + 0\cdot0_223382p - 0\cdot0_436254p^2) \\
 \text{" " NH}_4\text{Cl} &= a_w(1 + 0\cdot0_231583p + 0\cdot0_402842p^2) \\
 \text{" " MgCl}_2 &= a_w(1 + 0\cdot0_219907p + 0\cdot0_475182p^2) \\
 \text{" " NaNO}_3 &= a_w(1 + 0\cdot0_220573p - 0\cdot0_446156p^2) \\
 \text{" " Na}_2\text{CO}_3 &= a_w(1 + 0\cdot0_2162318p) \\
 \text{" " sugar} &= a_w(1 + 0\cdot0_2012827p + 0\cdot0_4016177p^2)
 \end{aligned}$$

Quinke found the following values (mgms./mm.) of α for solutions of organic substances :—

Solution of gall	(9%)	(sp. gr. = 1·0133)	$\alpha = 5\cdot076$
" " Venetian soap	(1/4000)	(" 0·9983)	2·681
" " "	(1/400)	(" 0·9992)	2·672
" " "	(1/40)	(" 1·0009)	2·563
" " sugar	(37·7%)	(" 1·1170)	8·182
" " tannin	(10%)	(" 1·0352)	5·857
" " gum arabic	(20%)	(" 1·0708)	7·603
" " isinglass	(very dilute)	(" 1)	6·790
" " gelatine	(very dilute)	(" 1)	7·277
" " agar agar	(very dilute)	(" 1)	7·842

The results obtained by Dorsey by the "ripple method" are highly instructive and suggestive; they are subjoined without alteration in the hopes that they may be of value in training students to work by this splendid method.

t = temperature of experiment.

n = frequency of tuning-fork employed to produce the ripples.

ρ = density of solution.

λ_1 = observed wave-length in terms of a scale each of whose divisions corresponded to 1·0328 cm.

T_t = surface tension at t° in dynes per cm.

$T_{18} =$ " " " 18° C. " " " "

TABLE LXXI_G.—Solutions of Sodium Chloride.

Traube investigated the behaviour of aqueous solutions of several organic liquids, and the results of his labours are given below. The numbers denote the heights to which the various mixtures ascended in capillary tubes of the same bore.

TABLE LXXI_{G₉}.—Aqueous Solutions of Fatty Acids.

Concentration. Grms. per Litre.	<i>h</i> .						
	Formic.	Acetic.	Propionic.	Butyric.	Isobutyric.	Isovaleric.	Caproic.
200	72·70	60·68	46·55	36·21

25	86·91	81·45	70·56	57·15	54·66	41·87	
12·5	89·05	85·10	77·56	67·07	64·57	53·06	
6·25					72·56	61·77	48·55
3·125					78·58	70·45	58·59

TABLE LXXI_{G₁₀}.—Aqueous Solutions of Alcohols.

Concentration. Grms. per Litre.	<i>h</i> .						
	Methyl Alcohol.	Ethyl Alcohol.	Propyl Alcohol.	Isopropyl Alcohol.	Butyl Alcohol.	Isobutyl Alcohol.	Isoamyl Alcohol.
200	61·05	48·71	35·07	35·50			
100	71·21	60·96	43·65	44·06			
50	78·04	71·37	54·70	54·60	38·46	40·03	
25	83·46	79·06	65·11	64·11	49·36	51·06	
12·5	87·45	83·74	74·32	72·14	60·45	62·07	45·57
6·25					69·07	71·20	56·48
3·125					76·64	77·06	67·08

From the preceding and some further investigations Traube compiled the following table for convenience of comparison.

Substance.	Grms. per Litre.	h .	Substance.	Grms. per Litre.	h .
Propionic acid, . .	100	53.76	Triethyl amine . .	40	41.26
Lactic „ . .	100	71.51	Propionitril, . .	40	63.19
Butyric „ . .	100	39.78	Ethyl ether, . .	40	53.33
Isobutyric „ . .	100	38.92	Oxalic „ . .	20	64.27
Oxyisobutyric „ . .	100	68.11	Anilin, . .	20	66.45
Ethyl alcohol, . .	100	60.96	Butyl alcohol, . .	12.5	60.45
Ethylene „ . .	100	85.84	Isobutyl „ . .	12.5	62.07
Propyl „ . .	100	43.65	Trimethyl carbinol, . .	12.5	68.11
Isopropyl „ . .	100	44.06	Isoamyl alcohol, . .	12.5	45.57
Glycerol, . .	100	90.03	Dimethylethyl carbinol, . .	12.5	60.02
Acetaldehyde, . .	50	75.50	Propyl alcohol, . .	12.5	74.32
Paraldehyde, . .	50	58.36	Allyl „ . .	12.5	81.57
Propylaldehyde, . .	50	62.52	Propyl acetate, . .	12.5	55.54
Acetone, . .	50	71.47	Allyl acetate, . .	12.5	64.25
Allyl alcohol, . .	50	66.46	Mercaptan, . .	5	85.30
Diethyl amine, . .	40	57.73	Benzaldehyde, . .	2.5	83.33

Putting m for the molecular weight of the organic acids, the values of h/m work out as follows:—

Grms. per Litre.	h/m .						
	Formic.	Acetic.	Propionic.	Butyric.	Isobutyric.	Isovaleric.	Caproic.
200	1.580	1.011	0.629	0.411			
100	1.721	1.144	0.726	452	0.442		
50	1.836	1.268	0.852	551	531		
25	1.889	1.358	0.954	649	621	0.410	
12.5	1.936	1.418	1.048	762	734	520	
6.25				847	825	606	0.411
3.125				910	893	691	0.499

From the preceding Traube concludes that, with two substances of molecular weights m_a and m_b respectively, if h_a and h_b represent the heights to which solutions of the same concentration of the two will ascend in the same capillary tube, and if h_a^1 and h_b^1 be the heights corresponding to another equal concentration, then—

$$\frac{h_a - h_a^1}{h_b - h_b^1} = \frac{m_a}{m_b}.$$

TABLE LXXIc*.—Capillarity Constants for Aqueous Solutions. (A) Quinke's Experiments.

TABLE LXXIG*.—Capillarity Constants of Aqueous Solutions.

(B) P. Volkmann's Experiments.

E = "Equivalent," according to Volkmann's nomenclature, really double the true chemical equivalent of the substance.

σ = Specific gravity of liquid at temperature of the experiments, water at 4° C. being taken as 1.

S = Weight of anhydrous substance dissolved in every 100 grms. of water (according to Gerlach's tables).

y = Number of salt "Equivalents" corresponding to every 100 "Equivalents" of water in solution.

a^2 and a with usual import.

By taking the values of S as abscissæ, and the corresponding values of α as ordinates, Volkmann found that he obtained points on a curve which approximately conforms to the equation ;—

$$xy = \alpha - 7\cdot50,$$

where y has the same value as in the table. The following are the instances given by him :—

2NaCl	$xy = \alpha - 7.44$; $x = 0.181$	2NaNO ₃	$xy = \alpha - 7.55$; $x = 0.102$
	$xy = \alpha - 7.50$; $x = 0.181$		$xy = \alpha - 7.50$; $x = 0.111$
2NH ₄ Cl	$xy = \alpha - 7.49$; $x = 0.130$	2KNO ₃	$xy = \alpha - 7.53$; $x = 0.102$
	$xy = \alpha - 7.50$; $x = 0.131$		$xy = \alpha - 7.50$; $x = 0.105$
2KCl	$xy = \alpha - 7.50$; $x = 0.160$	Na ₂ CO ₃	$xy = \alpha - 7.51$; $x = 0.112$
MgCl ₂	$xy = \alpha - 7.50$; $x = 0.197$	K ₂ CO ₃	$xy = \alpha - 7.50$; $x = 0.190$
CaCl ₂	$xy = \alpha - 7.45$; $x = 0.202$		$xy = \alpha - 7.50$; $x = 0.191$
	$xy = \alpha - 7.50$; $x = 0.204$	Na ₂ SO ₄	$xy = \alpha - 7.50$; $x = 0.153$
SrCl ₂	$xy = \alpha - 7.50$; $x = 0.187$	K ₂ SO ₄	$xy = \alpha - 7.50$; $x = 0.152$
BaCl ₂	$xy = \alpha - 7.43$; $x = 0.174$	MgSO ₄	$xy = \alpha - 7.50$; $x = 0.133$
	$xy = \alpha - 7.50$; $x = 0.174$		

The different values for the same substance are the results of different sets of experiments.

Rodenbeck's investigations with mixtures of two liquids, (alcohol and water; petroleum and chloroform; alcohol and chloroform; chloroform and ether; ether and petroleum), showed that if α = capillary constant of the mixture, α_1 , α_2 = capillary constant of each constituent, v_1 and v_2 = volume of each constituent in the mixture, then

$$\alpha = \frac{\alpha_1 v_1 + \alpha_2 v_2}{v_1 + v_2}.$$

Duclaux found that if aqueous solutions of two alcohols, or of two fatty acids, have the same surface tension, the percentage composition of the two solutions will have a constant ratio; the mean values for this ratio he found to be for—

Methyl alcohol/amyl alcohol,	33	Formic acid/acetic acid,	3
Ethyl alcohol/amyl alcohol,	17	Butyric acid/acetic acid,	0.10
Propyl alcohol/amyl alcohol,	9.2		
Butyl alcohol/amyl alcohol,	2.7		
Capryl alcohol/amyl alcohol,	0.061		

This means that a solution containing 1 per cent. of butyric acid will have the same surface tension as one containing 10 per cent. of acetic acid, etc.

Surface Tension between Two Liquids.

When a solid body (c) is in contact with two immiscible liquids a and b , which are also in contact with each other, if \mathcal{J} represent the angle made by the surface of c with that separating a and b , and if

$$\begin{aligned} \alpha_{ab} &\equiv \text{surface tension between } a \text{ and } b, \\ \alpha_{ac} &\equiv \text{,, ,, } a \text{ and } c, \\ \alpha_{bc} &\equiv \text{,, ,, } b \text{ and } c, \end{aligned}$$

then

$$\cos \mathcal{J} = \frac{\alpha_{bc} - \alpha_{ac}}{\alpha_{ab}};$$

or

$$\alpha_{ab} = (\alpha_{bc} - \alpha_{ac}) / \cos \mathcal{J}.$$

Quincke gives the following values for the liquids mentioned :—

Liquids.		α_a	α_b	α_{ab}
Mercury, .	Solution of $\text{Na}_2\text{S}_2\text{O}_8$ ($\sigma = 1.125$), .	55.03	7.90	45.11
" . .	Water,	55.03	8.25	42.58
" . .	Alcohol ($\sigma = 0.791$),	55.03	2.60	40.71
" . .	Chloroform,	55.03	3.12	40.71
" . .	Solution of HCl ($\sigma = 1.1$), . .	55.03	7.15	38.41
" . .	Carbon disulphide,	55.03	3.27	37.97
" . .	Olive oil,	55.03	3.76	34.19
" . .	Petroleum ($\sigma = 0.798$),	55.03	3.23	28.94
" . .	Turpentine,	55.03	3.03	25.54
Water, . .	Carbon disulphide,	8.25	3.27	4.26
" . .	Petroleum,	8.25	3.23	3.83
" . .	Chloroform,	8.25	3.12	3.01
" . .	Olive oil,	8.25	3.76	2.09
" . .	Turpentine,	8.25	3.03	1.18
Olive oil, . .	Alcohol,	3.76	2.60	0.23

If in the last equation c represents a fluid, i.e. a gas or a liquid, the whole expression will require considerable modification. If c denote air, a and b any two liquids—say a drop of b on the surface of a —and if

θ_1 = the angle between the surface separating a from c and that separating b from c outside both liquids ;

θ_2 = the angle between the surface separating a from b and that separating b from c ;

θ_3 = the angle between the surface separating a from b and that separating a from c ;

α_{ab} = surface tension between a and b ;

α_{ac} = surface tension between a and c ;

α_{bc} = surface tension between b and c ;

then

$$\alpha_{ac}/\sin \theta_2 = \alpha \sin \theta_3 = \alpha_{ab}/\sin \theta_1,$$

if there exist a state of equilibrium, and the three magnitudes α_{ac} , α_{bc} and α_{ab} may be represented by the three sides of a plane triangle, and the sum of any two of them must be greater than the third. So far, no instance has been observed where three fluid surfaces meeting along a common line can be in equilibrium—one of the three tensions α_{ac} , α_{bc} and α_{ab} being always greater than the sum of the other two. One pure liquid would always spread over the whole exposed surface of another ; thus, as shown by Quincke, a drop of pure water will spread over the surface of pure mercury.

Watson found the following values for α in dynes/cm. at 0°C . :—

Water/air,	76.62	77.59
Mercury/air,	439.07 (?)	487.04
Petroleum/air,	26.45	
Benzol/air,	23.05	
Water/petroleum,		35.38
Water/benzol,		33.79
Mercury/water,	367.90	375.10
Mercury/alcohol,	354.67	368.63

Here we see water/air > water/petroleum + petroleum/air ; the same thing is observable from Quincke's numbers already given.

TABLE LXXII.

In 1888 Quincke found the following values for the surface tension of the substances named against air (α_a), and against water (α_{ab}) or other liquid where stated.

Liquid.	Specific Gravity.	α_a	α_{ab}
Soda solution, 0.25 per cent.,	1	8.418	0
Water,	1	8.253	0
Glycerol,	1.2535	7.348	0
Rubsen oil,	0.9151	3.348	1.564
Rapeseed oil,	9130	3.340	1.700
Olive oil,	9152	3.760	2.296
Almond oil,	9173	3.515	2.370-1.761
Cod liver oil,	9251	3.391	0.878-0.700
Castor oil,	9633	3.830	1.624
Almond oil + chloroform,	1.0123		1.892-0.622
Chloroform,	1.4878	3.120	3.010
Carbon disulphide,	1.2687	3.274	4.256
Benzol,	0.8985	3.123	1.969
Petroleum,	7977	3.233	3.834
Turpentine,	8867	3.033	1.177
Alcohol,	7904	2.354	0
Ether,	7200	1.740	1.255
Egg albumen,	1.0365	5.934	0
" "	1.0384	5.370 to	0
" "		4.913	0
Aqueous solution of gall (9 per cent.),	1.0133	5.076	0
" " Venetian soap (1/4000),	0.9983	2.681	0
" " " (1/400),	0.9992	2.672	0
" " " (1/40),	1.0009	2.563	0
" " sugar, 37.7 per cent.,	1.1170	8.182	0
" " tannic acid, 10 per cent.,	1.0352	5.857	0
" " gum arabic, 20 per cent.,	1.0708	7.603	0
" " isinglass, }	1	6.790	0
" " gelatine, } very dilute,	1	7.277	0
" " agar agar, }	1	7.842	0
Rapeseed oil/egg albumen,			0.710
" " /glycerol,			1.415
" " /aqueous solution of isinglass,			2.140-1.688
Olive oil/diluted alcohol,			0.693
Almond oil/egg albumen,			0.701
" " /NaCl solution, 1 per cent.,			1.261
Almond oil + CHCl ₃ /soda solution,			0.678-0.119
" " /soap solution,			0.257
Cod liver oil/NaCl solution, 1 per cent.,			0.470
" " /egg albumen,			0.400

This investigator found that the surface tension was practically *nil* between the following pairs of liquids:—

Alcohol, alcoholic solution; alcohol, ether; alcohol, turpentine; benzol, chloroform; benzol, rapeseed oil; glycerol, olive oil; glycerol, almond oil; glycerol, cod liver oil; carbon disulphide, ether; carbon disulphide, benzol; carbon disulphide, chloroform; carbon disulphide, olive oil; carbon disulphide, turpentine; petroleum, rapeseed oil; turpentine, olive oil; water, aqueous solutions.

Cantor (1892) gives the following values for the surface tensions between

Mercury and benzol at 20° C., 34·83 mgr./mm.

" " " " 72° C., 28·45

" " amyl alcohol, 25° C., 26·67

TABLE LXXII.—Surface Tension of Fused Metals, etc.

Note.—Where no numbers are given in the temperature column it is to be understood that the experiments were conducted at or very close to the fusion point of the substance.

Quinke suggested that for all substances at or near their solidifying points,—

$$\alpha^2 = n \times 4.3;$$

and he gives,—

$$n = 1$$

for Se, Br, S, P, NaBr, KBr, AgBr, and KI; experimental results range from

$$3.42 \text{ to } 4.84:$$

$$n = 2$$

for Hg, Pb, Bi, Sb, NaNO₃, KNO₃, LiCl, NaCl, KCl, CaCl₂, SrCl₂, BaCl₂, AgCl, cane sugar, grape sugar, pectin sugar, spermaceti, paraffin, and wax; experimental results range from 7.18 to 9.49;

$$n = 4$$

for Pt, Cd, Sn, Au, Ag, Cu, Li₂CO₃, Na₂CO₃, K₂CO₃, Na₂SO₄, K₂SO₄, microcosmic salt, borax, glass, and water; experimental results range from 14.8 to 17.9;

$$n = 6$$

for Pd, Zn, and cast iron; experimental results range from 25.3 to 27.1:

$$n = 12 \text{ for Na; experiment gave 53 instead of 51.6;}$$

$$n = 20 \text{ for K; experiment gave 85.7 instead of 86.}$$

Traube's numbers (*Ber.*, xxiv. p. 3074 *et seq.*) have been employed to calculate the values of α on the supposition that for water at 0° C., $\alpha = 7.791$, more closely approximate to the results of the drop method than 7.6 given by him.

Siedentopf obtained his results by accurately determining the radius of a flattened drop (T) and the radius of curvature of the drop surface (μ), and calculating by means of the following formula—

$$\alpha^2 = T^3 / kx(\mu - T)$$

where $x = T/\mu$, and

$$k(x) \equiv 2.124 + 1.0178x + \frac{1}{8} \sqrt{1 - 16(x - \frac{2}{3})^2}.$$

If σ = density of the molten substance,
 σ_0 = " " medium in which the capillary surface is formed,
 then,

$$\alpha = \alpha^2(\sigma - \sigma_0)/2.$$

The method is elegant and exceedingly useful, so the experimental data on which he based his calculations are appended.

For mercury at 16° C.—

T	μ
3.994	7.4509
4.047	7.6537
4.1175	7.9002
4.165	8.0943
4.2425	8.4296
4.318	8.7778
4.365	8.9422
4.4015	9.1231

For tin—

	mm.	mm.
at 277° C.	T = 4.807	μ = 6.932
290	4.927	7.231
432	5.018	7.469
513	4.655	6.6586

For bismuth—

at 346° C.	T = 4.0306	μ = 6.664
511	4.0735	6.858

For lead—

at 389° C.	T = 4.0307	μ = 6.3674
498	4.0359	6.4304

For cadmium—

at 365° C.	T = 4.087	μ = 5.1683
431	4.5709	6.1203

For alloy of 80 parts Sn + 20 parts Bi—

at 225° C.	T = 4.261	μ = 5.9437
339	4.424	6.3391

For alloy of 62.5 parts Sn + 37.5 parts Bi—

at 266° C.	T = 4.227	μ = 6.0052
407	4.2342	6.0529

For alloy of 53.1 parts Sn + 46.9 parts Bi—

at 175° C.	T = 4.6782	μ = 7.3240
296	4.2285	6.1853

For alloy of 37 parts Sn + 63 parts Bi—

at 242° C.	T = 4.227	μ = 6.3883
373	4.2124	6.4049

For alloy of 19.7 parts Sn + 80.3 parts Bi—

at 281° C.	T = 4.1821	μ = 6.5820
417	4.2194	6.7493

This investigator gives the following interpolation and extrapolation formulæ :—

For mercury,	$\alpha_\theta = 46.29(1 - 0.0_8 351\tau) :$	$\alpha_\theta^2 = 6.769(1 - 0.0_8 185\tau) :$	$\tau = \theta + 39$
„ tin,	$62.43(1 - 0.0_8 272\tau) :$	$17.87 (1 - 0.0_8 164\tau) :$	$\theta - 226$
„ bismuth,	$43.78(1 - 0.0_8 233\tau) :$	$8.755(1 - 0.0_8 117\tau) :$	$\theta - 271$
„ lead,	$51.94(1 - 0.0_8 287\tau) :$	$9.778(1 - 0.0_8 166\tau) :$	$\theta - 325$
„ cadmium,	$84.85(1 - 0.0_8 419\tau) :$	$21.24 (1 - 0.0_8 255\tau) :$	$\theta - 318$
„ alloy (1),		$15.9 (1 - 0.0_8 108\tau) :$	$\theta - 195$
„ „ (2),		$14.6 (1 - 0.0_8 119\tau) :$	$\theta - 140$
„ „ (3),		$13.4 (1 - 0.0_8 126\tau) :$	$\theta - 140$
„ „ (4),		$12.25 (1 - 0.0_8 169\tau) :$	$\theta - 140$
„ „ (5),		$10.6 (1 - 0.0_8 161\tau) :$	$\theta - 225$

θ = temperature on ordinary Centigrade scale.

He also found that if m_1, m_2 respectively denote the percentage of each ingredient in a binary alloy, and if α_1^2, α_2^2 be the specific cohesion of the ingredients separately, then—

$$\alpha_m^2 = \text{specific cohesion of alloy} = \frac{m_1 \alpha_1^2 + m_2 \alpha_2^2}{m_1 + m_2},$$

and with none of the preceding alloys did the calculated value differ as much as 1.5 per cent. from that experimentally determined.

Siedentopf's formulæ for mercury, gave for that liquid at 0°C. ,

$$\alpha_0 = 45.656 \text{ mgm./mm.}$$

$$\alpha_0^2 = 6.720$$

If α^2 is calculated from α_0 and the density of mercury at 0°C. , we get

$$\alpha^2 = 6.716.$$

TABLE LXXIJ.—Surface Tension, etc., of Liquefied Gases.

In his researches on liquid air Kipp found that it loses nitrogen readily, so that with age its physical properties approximate more and more closely to those of liquid oxygen. The following are the mean values of the experimental results obtained with liquid air of the age stated :—

Age in minutes.	Density.	α in dynes/cm.
75	1	10.24
140	1.05	10.36
260	1.1	11.28
450	1.131	13.35

Other series gave—

Age in minutes.	Density.	α in dynes/cm.	Age in minutes.	Density.	α in dynes/cm.
(A) 115	1.026	10.78	150	1.047	11.98
135	1.038	11.91	160	1.053	12.07
145	1.045	12.38	(C) 67	0.995	11.07
240	1.09	12.59	112	1.024	11.28
265	1.099	12.45	182	1.065	12.00
280	1.104	12.79	222	1.083	12.53
295	1.108	12.91	257	1.095	12.96
320	1.116	13.05	274	1.103	13.01
352	1.124	13.14	294	1.108	13.12
370	1.1245	13.17	312	1.114	13.24
385	1.127	13.23	324	1.118	13.30
410	1.13	13.18	340	1.122	13.31
(B) 133	1.037	11.42			

Grunmach gives the following values for liquid air, or rather the liquid residue left at about -190°C .

Percentage of liquid oxygen in mixture,	49.9	63.9	65.3	66.8	67.6	74.4	76.4	76.7
Values of α in dynes/cm.,	11.61	11.89	12.05	11.90	11.91	12.23	12.51	12.63

This investigator also gives what he calls the corresponding values of α^2 , but some curious error must have crept into his calculations, as his numbers involve a *decrease* in density with an *increase* in the percentage of oxygen.

Forsch found the surface tension of liquid air—out of which a great deal of the nitrogen had already evaporated—to be about 1.23 mgm./mm. or 12.08 dynes/cm., corresponding almost exactly to the value found by Grunmach for the liquid containing 65.3 per cent. of oxygen.

Grunmach gives also the following values for α :—

SO ₂	at -25°C . ($\sigma_t = 1.5016$)	α in dynes/cm.,	33.285
NH ₃	„ -29 { 0.6703}		41.778
Cl ₂	„ -72 { 1.6452}		33.6493
Pictet's liquid	„ -33		35.065
64% SO ₂ + 44% CO ₂	„ -60 (1.564)		38.209 (15 years old)

TABLE LXXI_k.—Surface Tension and the Media in contact with the Liquid.

Lord Kelvin, the first to apply the principles of thermodynamics to the phenomena of capillarity and surface tension, proved that when a liquid is in contact with no gaseous medium other than its own vapour

$$p = P \pm \frac{\alpha\rho}{\sigma - \rho} \left(\frac{1}{r} + \frac{1}{r_1} \right) \quad (1)$$

where

p = pressure of vapour at a point in the curved surface formed within a capillary tube dipping in the liquid;

P = pressure of vapour over horizontal surface of liquid;

α = surface tension of liquid;

σ = density of the liquid;

ρ = density of the vapour;

r and r_1 = principal radii of curvature at the point where the vapour pressure is p .

Where the tube is very fine, the meniscus becomes practically a portion of the surface of a small sphere, and $r=r_1$, so—

$$p = P \pm \frac{\sigma \rho}{r} \cdot \frac{2}{r} = P \pm \frac{2\sigma}{r} \cdot \frac{\rho}{\sigma - \rho} \quad (2)$$

If h = height to which the liquid would be raised or depressed within the tube in virtue of the curvature of its surface,
and h = height of homogeneous atmosphere of vapour capable of exerting the pressure P ,

$$p = P (1 - h/h) \quad (3)$$

Equation (2) may be written—

$$p = P \pm \frac{2\sigma}{r\sigma} \cdot \frac{\rho}{1 - \rho/\sigma} = P \pm h\rho$$

very nearly; or if the pressures are expressed in absolute units,

$$p = P \pm gh\rho \quad (4)$$

When ρ is insignificant compared with σ we have $\log (p/P) = - (2\sigma/r)(1/RT)$; where RT has the same significance as in the case of the gas equation, $pv = RT$, i.e. the pressure on the vapour side of the meniscus will be $P \pm gh\rho$, and the pressure on the liquid side of the meniscus must be $P \pm gh\sigma$. The difference between these two pressures, i.e.,

$$gh(\sigma - \rho) = 2\sigma/r \quad (5)$$

so

$$\alpha = ghr(\sigma - \rho)/2 \quad (6)$$

This equation holds for all media, and not merely for the vapour of the liquid itself. In general ρ is so small compared with σ that it may be neglected, and if $r=1$, h becomes α^2 and we get as before;—

$$\alpha = ga^2\sigma/2,$$

or in gravitation units

$$\alpha = a^2\sigma/2$$

Stöckle (curvature of drop method) found that the surface tension of pure mercury varied considerably in different media, but the tension rapidly diminished owing to the condensation of the gas on the surface of the liquid. The following are his results:—

Medium.	Pressure.	Temperature.	Values of α in mgm./mm.	
			On Projection.	An hour afterwards.
Vacuum,	0.034 to 0.001 mm.	15° C.	44.4	44.4
Hydrogen,	Atmospheric pressure	21	47.9	44.2

The diminution in the value of the surface tension takes place very rapidly in hydrogen, but slowly in the comparatively inert nitrogen.

G. Meyer sought to eliminate the effect of gaseous condensation by measuring the waves on a jet of mercury projected into various gases. He obtained the following values for α :—

In air,	51.5 mgm./mm.
„ oxygen,	51.4
„ nitrogen,	50.5
„ carbon dioxide,	49.6
„ hydrogen,	56.5

These are much higher than Stöckle's initial values, the reason being that Meyer's measurements were made with an absolutely clean surface of mercury, while in the other case a short time must elapse before any measurement could be made, and a certain amount of surface contamination must have occurred.

P. Volkmann, experimenting in moist air, under a pressure of 750 millimetres of ice-cold mercury, obtained the following results with pure water at various temperatures :—

° C.	$\sigma - \rho$.	Values of α .		Value of α^2 .
		Mgms./mm.	Dynes/cm.

17.5	86512	2.906	28.52	6.719

For most liquids σ and ρ differ so widely, at anything like ordinary temperature and under ordinary atmospheric pressure, that ρ may be left out of our calculations without

causing any appreciable error; but under increased pressures and at increased temperatures, more especially when approximating to the "critical state," it must be taken into account. A. van Edlip determined the height (H) to which a mixture of ethylene (critical temperature about 10° C. and critical pressure about 51 atmospheres) and methyl chloride (critical temperature about 142° C. and critical pressure about 73 atmospheres) would, under various conditions, ascend in a tube whose radius was 0.1 mm.

they give the empirical equation—

$$K^2 = V_0(1 + \alpha t)/v\beta,$$

K denotes Laplace's constant;

β " the compressibility;

V_0 " the volume at $t^\circ \text{C.}$ under 1 atmosphere pressure of 1 kgm. of the vapour of the liquid concerned;

v " the volume of 1 kgm. of the liquid or solution at $t^\circ \text{C.}$

TABLE LXXI.

The following table gives the actual experimental results obtained by those investigators, as far as density, compressibility, etc., are concerned; unfortunately they have not given us the results referring to surface tension.

m = molecular weight of the dissolved substance;

p = percentage of substance in the solution;

n = number (relative) of molecules of substance to 1 grm. of water = $\frac{1,000,000}{m} \cdot \frac{p}{100-p}$;

d = density of solution at $t^\circ \text{C.}$

c = relative compressibility determined at $t_1^\circ \text{C.}$

TABLE LXXIo.—Surface Tension, Critical Temperature, Molecular Dimensions, etc.

Eotvös has shown that for many liquids $d(av^{\frac{2}{3}})/dt$ is a magnitude independent both of the nature of the liquid and of the temperature, v denoting the "molecular volume" of the liquid, *i.e.* the molecular weight divided by the density; or "the rate of variation with the temperature of the product of the surface tension of a liquid by its molecular domain raised to the power $\frac{2}{3}$ is the same for all liquids." From this it follows that if θ denote the temperature at which α , and consequent $av^{\frac{2}{3}}$, = 0, then,—

$$av^{\frac{2}{3}} = k(\theta - t).$$

Ramsay puts this equation in a slightly different form—

$$av^{\frac{2}{3}} = k(\vartheta - d - t) = k(\tau - d),$$

where ϑ is the critical temperature, d a constant, and $\tau = \vartheta - t$, or the temperature reckoned downwards from the critical temperature. When pretty close to the critical temperature the equation given by Rose-Innes—

$$av^{\frac{2}{3}} = k(\tau - d) + kd/10^{\lambda\tau}$$

(where λ = a constant not differing widely from 0.03), yields results more in accordance with experimental ones.

Eotvös found

$$\begin{aligned} d(av^{\frac{2}{3}})/dt &= -k = -0.227, \text{ when } \alpha \text{ is given in mgms./mm.} \\ &= -2.227 \text{ when } \alpha \text{ is given in dynes/cm.} \end{aligned}$$

Therefore—

$$av^{\frac{2}{3}} = 2.227(\theta - t) = 2.227(\vartheta - d - t) = 2.227(\tau - d).$$

As $v = M/\sigma$, this last equation gives us—

$$M = \sigma \sqrt{\left(\frac{2.227(\theta - t)}{\alpha}\right)^3} = \sigma \sqrt{\left(\frac{2.227(\tau - d)}{\alpha}\right)^3},$$

giving us a method for determining the molecular weight of a liquid body from its surface tension. For this purpose we need not determine θ , τ or d experimentally; determinations of α at two or three temperatures will supply us with all the data we require for our calculations.

If we knew the true values of M and σ , the value of k as calculated from them should be the same under all conditions; but σ we know varies with the temperature, and so also does M , as unquestionably the degree of "association" varies somewhat with the temperature. Eotvös found that for liquid water between 100° C. and 200° C., M worked out as 36; *i.e.* the molecular formula of liquid water between 100° C. and 200° C. is H_4O_2 ; below 100° C. it is still more complicated, the mean value of molecular weight of liquid water at 85° C. being 50; at 65° C., 53.3 ($\equiv H_5O_3$ very nearly); at 45° C., 56; at 25° C., 62; and at 5° C., 69 very nearly (approximately H_8O_4).

Grunmach, using the value 2.27 for k , found the following molecular weights for liquefied gases:—

Sulphur dioxide = 65.66 ($\equiv SO_2$ practically).
 Ammonia = 17.10 ($\equiv NH_3$ „ „).
 Chlorine = 92.14 ($7xCl_2 + 3xCl_4$ very nearly).

Ramsay and his colleagues took 2.1209 as a fair average value for k . If we put $M = \mu x$, M representing the mean value of the weight of a liquid molecule, μ the molecular weight of the homogeneous vapour, x = the association factor, and k = experimental value, for any liquid;—

$$2.1209/k = x^3.$$

Values of θ , k , d , x , and M . (Ramsay, etc.)

„ . . .	243.1	„ 150 1.569		1.57	72.2

Eotvös had found the following values for k (α being expressed in mgms./mm.) :—

Ethyl ether,	6° C. to	62° C.	0.228	Sulphur dioxide,	2° C. to	60° C.	0.230
"	62	120	0.226	Carbon dioxide,	3	31	0.228
"	120	190	0.221	Ethyl alcohol,	21	78	0.104
Ethylene bromide,	20	99	0.227	"	78	108	0.136
"	99	213	0.232	"	108	138	0.159
Chloroform,	20	60	0.230	"	138	168	0.183
Mercury methide,	20	99	0.228	"	168	199	0.202
Carbon-oxychloride,	3	63	0.231	"	199	236	0.226
Carbon disulphide,	22	78	0.237				

For acetic acid, if we put its molecular formula $C_2H_4O_2$, k works out as .132 between 21° and 160° C. and only .138 between 160° and 230° C.; but if we take it as $C_4H_8O_4$, then $k = 0.211$.

There is something strange about the numbers for the first substance in the preceding table. They ought to have increased with rise of temperature; they diminish instead.

From the results obtained with acetic acid, methyl alcohol and ethyl alcohol, it looks as if the superior limit of α , at least for the liquids mentioned, is 4 : that is,—

M is never greater than 4α .

TABLE LXXI_F.

As already stated, the Rose-Innes equation answers better at temperatures approaching θ ; the following results given by Ramsay and Shields emphatically show this. The values of k and d have been already given.

Ethyl Oxide. $\lambda = 0.03$.				Benzol. $\lambda = 0.029$.

The simpler formula $\alpha v^{\frac{2}{3}} = k(\tau - d)$ gives numbers that do not nearly agree with the experimental results when τ is less than 44.5 for methyl oxide, 14 for methyl formate, 38.5 for benzol, or 41 for ethyl acetate: thus with the first substance if $\tau = 14.5$ we get, according to the formula, $\alpha v^{\frac{2}{3}} = 13$ instead of 19.9 as given by experiment, while $\alpha v^{\frac{2}{3}}$ is according to the formula -8.7 when τ is 4.5.

As $v^{\frac{2}{3}}$ is proportional to the mean linear distance between the molecules, $nv^{\frac{2}{3}}$ will represent an area containing n molecules, or rather on which n molecules lie, and if p represent the vapour pressure on a unit area,

$$pnv^{\frac{2}{3}}$$

will represent the total vapour pressure on such a surface.

Further, $mv^{\frac{2}{3}}$ represents a line on which lie m molecules, and the total surface tension across a line will be $amv^{\frac{2}{3}}$. Eotvos assumes that for any two liquids—

$$\alpha_1/p_1v_1^{\frac{2}{3}} = \alpha_2/p_2v_2^{\frac{2}{3}};$$

or

$$\alpha_1v_1^{\frac{2}{3}}/p_1v_1 = \alpha_2v_2^{\frac{2}{3}}/p_2v_2.$$

According to van der Waals, when two substances are in the "corresponding states,"

$$V_1/V_2 = v_1/v_2 = p_2T_1/p_1T_2$$

(V denoting the molecular volume of a substance in the state of vapour = μ/ρ). Under such conditions therefore we get

$$\alpha_1v_1^{\frac{2}{3}}/T_1 = \alpha_2v_2^{\frac{2}{3}}/T_2$$

This, like most equations relating to "corresponding states," gives good results when compounds of analogous chemical structure are compared, but breaks down pretty thoroughly if we attempt to apply it to substances belonging to totally different chemical classes; e.g. benzol and alcohol, or benzol and ether.

This quantity $\alpha\sigma$ may be termed "molecular superficial energy": its temperature coefficient k , according to Dutoit and Friederich, does not vary with the temperature in "normal" liquids but does so in "abnormal" ones. They give the following values for k :—

Metaxylol,	2.10	Paratoluidin,	1.72
Mesitylene,	2.15	Dimethyl-o-toluidin,	2.49
Durol,	2.14	Diphenyl-amine,	2.57
Pentamethyl benzol,	2.165	Pyridin,	2.17
Hexane,	2.11	Quinolin,	2.43
Diphenyl,	2.22	Acetonitril, 16° to 90° C.,	1.50 to 1.56
Naphthalin,	2.29	Propionitril, 13° to 76°,	1.67 to 1.74
Diphenylmethane,	2.23	Butyronitril, 17° to 96°,	1.89
Anilin,	1.60 to 2.05	Paratoluol, 57° to 180°,	1.88 to 2.05
Methylanilin,	1.99 to 2.08	Diphenyl-ethane (sym.),	2.49
Ethylanilin,	2.22	Acetone,	1.83
Dimethylanilin,	2.39	Methyl-ethyl-ketone,	1.85
Diethylanilin,	2.34	Acetophenone,	2.14
Orthotoluidin,	2.05	Benzophenone,	2.63

Verschaffelt finds that for—

Liquid CO₂ between -24°·3 and + 8°·9 C., $k = 2.223$;

" " " " + 8°·9 " " 15°·2 C., " = 2.222;

" N₂O " " -24° " " +14°·4 C., " = 2.198.

Eotvös's original idea seems to have been that as with normal gases, at temperatures equally removed from the absolute zero, the product of the pressure by the molecular volume is the same for all gases, so for all normal liquids, at temperatures equally removed from their critical points, the product of the surface energy by the molecular area is the same for all liquids. As shown by Ramsay and his fellow-workers, this can at best be looked upon as a very rough approximation to the truth, and even the final value of k adopted by these investigators is far too low. For liquids where "association" is entirely absent, k should be of the maximum value, and, unless we suppose that some liquids contain a fair proportion of associated molecules, we must set this value nearer to 2.500 than 2.121. Guye and Baud investigated this question in connection with some twelve substances, and the results of their investigations are given. The last two columns in the following table give the values of k and α as calculated by the compiler from the data obtained by these Genevan investigators; their methods of computation seemed in some respects undesirable.

TABLE LXXIq.—Values of α , k , α , etc. (Guye and Baud.)

As the degree of association is in most cases an indirect function of the temperature, an approximation has been made to the value of β (\equiv temperature when $\alpha = 0$) from the results obtained at the highest temperatures. From this value of β the values of k for the various temperatures have been calculated by means of the equation

$$\alpha v^{\frac{2}{3}} = k(\beta - t).$$

These results are given in the eighth column. The values given in column six were obtained for each interval of temperature by the formula—

$$k = \frac{\alpha_1 v_1^{\frac{2}{3}} - \alpha_2 v_2^{\frac{2}{3}}}{t_2 - t_1}.$$

The values of x given in the seventh column have been computed by means of the formula

$$\text{Log } x = \frac{3}{2} (\log 2.121 - \log k)^{\frac{1}{2}}$$

those in the ninth column from

$$\text{Log } x = \frac{3}{2} (\log 2.4 - \log k).$$

Anisol and phenetol evidently belong to the class of substances whose "association" tends to increase with a rise of temperature, at least up to a certain point.

Dutoit and Friederich give, as a fairly general approximation,

$$\pi = Q\alpha / \sqrt[3]{\phi},$$

where π = critical pressure, ϕ = critical molecular volume, and Q = a constant: for many substances Q is not found to be far from 11.1.

For liquefied gases, etc., Verschaffelt finds:—

$$\alpha = A (1 - m)^B$$

where m = "reduced temperature," i.e. $t^\circ/3^\circ$ and A and B are constants. Various values have been assigned to B ; van der Waals puts it = $3/2$; Ramsay and Shields find $B = 1.23$ and Verschaffelt finds $B = 1.521$. The following values are given:—

Substance.	Log A.	Value of B.
Carbon dioxide, . . .	1.924	1.311
Nitrous oxide, . . .	1.945	1.33
Carbon tetrachloride, . .	1.811	1.228
Ethyl oxide, . . .	1.761	1.270
Ethyl acetate, . . .	1.810	1.230
Benzol, . . .	1.839	1.230
Chlorbenzol, . . .	1.827	1.214

De Heen gives the following equation,—

$$r = 0.0215\alpha M/\sigma,$$

where r denotes the radius of the "sphere of influence" of the liquid molecule; and he calculated the values of r for the following six substances:—

Water,	$r = 297 \times 10^{-9}$ cm.
Sulphuric acid,	718 " "
Platinum @ 2000° C.,	3727 " "
Silver @ 1000° C.,	991 " "
Lead @ 330° C.,	1838 " "
Mercury,	1740 " "

Kistiakowsky gives the following expression for the molecular weight of a liquid,—

$$M = (2.39/ghr\sigma^{\frac{1}{3}})^{\frac{2}{3}},$$

where

θ = Absolute boiling point ;
 h = Height to which liquid ascends in tube of radius r ;
 g = Acceleration due to gravitation ;
 σ = Density of liquid.

TABLE LXXI_R.—Surface Tension and Chemical Constitution.

Since 1866, when Mendelejeff made his first attempt, many investigators have sought to trace the relations between the surface tensions of liquids and their chemical constitution. One of the most persistent and successful investigators in this direction has been R. Schiff, and it was in connection with this question that he introduced the new constant $N(=a/M)$ into surface tension literature (see Table LXXI_F); for the sake of convenience Schiff puts $N=1000a/M$. He found that the influence of all constituent atoms can be expressed in terms of that of one hydrogen atom; thus the first substance given in the table referred to is hexane, and corresponds to twenty-six hydrogen "equivalents," as every carbon atom corresponds to 2H. We are given the equation—

$$N = \frac{1}{n} \cdot e^{(6.483 - 0.0168n)}$$

$$\text{Log}_e N = 6.483 - 0.0168n - \log_e n;$$

and in ordinary logarithms

$$\text{Log } N = 2.81553 - 0.007296n - \log n.$$

This equation gives 16.2 as the value of N for hexane, and the experimental results obtained by Schiff give 16.1.

The values for the various elements, as found by this investigator, are the following :—

C \equiv 2H in nearly all compounds except in free acids.

\equiv 3H in free acids.

O \equiv 3H (oxygen linked to two carbon atoms, and also in several ring complexes, seems to exert no influence, so here O \equiv 0H).

Cl \equiv 7H generally.

\equiv 6H when there are several chlorine atoms joined to different carbon atoms; also in the side chains of benzene compounds.

Br \equiv 13H.

\equiv 11H in ethylene bromide, propylene bromide, and free bromine.

I \equiv 19H.

N \equiv 0H (having no influence) in primary amines.

\equiv 1H in secondary amines.

\equiv 2H in the tertiary amines.

\equiv 2H in nitro-groups.

\equiv 3H in the CN group.

S \equiv 5.5H.

P \equiv 5H when trivalent.

\equiv 4H when pentavalent.

It will be readily admitted that the relative values of these elements calculated from surface tension investigations ought to be, at least very nearly, in the same ratios as those computed from the molecular volumes (see Table LXX_P, pages 684–686), and it is very

interesting to notice how closely the different sets of values agree in this respect. Kopp's values work out very nearly as follows:—

$C \equiv 2H$.
 $5N \equiv 2H$ in ammonias (? primary amines).
 $N \equiv 3H$ in cyanides.
 $5N \equiv 8H$ in nitro derivatives.
 $5O \equiv 7H$ in hydroxyl group.
 $5O \equiv 11H$ in carboxyl group.
 $P^{iii} < 5H$ (slightly).
 $P^v < 4H$ (").
 $Cl > 4H$.
 $Br > 10H$.
 $S > 5H$.

Traube's values also show interesting coincidences:—

$C \equiv 3H$.
 $N \equiv 0.5H$ in ammonias.
 $\equiv 3H$ in cyanides.
 $\equiv 2.5H$ to $3H$ in nitro derivatives.
 $\equiv 4H$ in tertiary amines.
 $8O \equiv 1H$ in hydroxyl groups.
 $O \equiv 0.75H$ when O is "extra-radicle."
 $\equiv 2H$ in carboxyl groups.
 $P^{iii} \equiv 5H$ }
 $P^v \equiv 9H$ }
 $S \equiv 5H$.

The series $I \equiv 19H$, $Br \equiv 13H$, and $Cl \equiv 7H$, might lead us to expect that F would correspond to H ; the volume value of fluorine as found by Thorpe is considerably less than double that assigned to hydrogen.

The values of N , computed from Schiff's investigations, are given in Table LXXXI \bar{f} ; it will be seen that they are practically identical for all isomeric substances.

Sutherland concluded that "in compounds containing C , O , and H , the molecule may be considered to have a volume to which each atom of H contributes an amount very small in comparison with that contributed by an atom of O or C The volume of such a molecule can be expressed in terms of that of a carbon atom, and the *parameter A varies inversely as the surface of the molecule.*" From this and the equation given by Eotvös he concludes that

$$a = kA\sigma^{\frac{1}{3}}M^{\frac{2}{3}},$$

where k is approximately the same for all liquids. This investigator finds that an atom of oxygen directly linked to two atoms (O^i) has the same effect on the molecular volume as two atoms of carbon, while an atom directly united to only one atom (O^{ii}) has the same effect as three atoms of carbon; *i.e.*—

$$\begin{aligned} O^i &\equiv 2C \\ O^{ii} &\equiv 3C \end{aligned}$$

If a molecule contain x atoms of carbon, y atoms O^i , and z atoms of O^{ii} , if we put

$$x + y + z = n,$$

we get

$$\text{molecular volume, } v \propto n,$$

and $av^{\frac{1}{3}} \propto an^{\frac{1}{3}}$;

but $n^{\frac{1}{3}} \propto$ surface of the molecule, and therefore $A^{-1} \propto n^{\frac{1}{3}}$ and $An^{\frac{1}{3}} = \text{a constant}$;

$$\therefore kAn^{\frac{1}{3}} = \text{a constant}.$$

Sutherland gives also the following values as approximation for elements other than oxygen :

$\text{Cl} \equiv 5\text{C}$ or 6C .

$\text{N} \equiv 0.8\text{C}$ to 1C in amines.

$\text{N} \equiv 0.6\text{C}$ in NO_2 or NO_3 groups.

In cyanides the value of N seems to diminish as the molecular weight of the cyanide increases.

Sutherland's numbers do not agree very closely with his theory, but they are very suggestive. They are given below.

Substance.	Formula.	n .	kA .	Mean Value of kA .	$kAn^{\frac{2}{3}}$.

TABLE LXXI_R.—continued.

Substance.	Formula.	n. •	kA.	Mean Value of kA.	kAn ³ .
Isobutyl chloride, . . .	$C_4H_8O^iO^{ii}$	9	0.540	0.525	2.27
Dimethyl acetal, . . .	C_4H_9Cl		525		
Anisol, . . .	$C_6H_5O^iCH_3$	9	521		
	C_9H_{12}	9	515		
Allyl acetate, . . .	$C_5H_8O^iO^{ii}$	10	0.503	0.468	2.17
Epichlorhydrin, . . .	$CH_3ClC_2H_3O$		495		
	$C_5H_{10}O^iO^{ii}$	10	495		
Carbon disulphide, . . .	CS_2		491		
Isoamyl chloride, . . .	$C_5H_{11}Cl$		491		
Ethyl nitrate, . . .	$C_3H_5NO_3$		484		
Decane, . . .	$C_{10}H_{22}$	10	473		
Phenetol, . . .	$C_6H_5O^iC_2H_5$	10	471		
	$C_{10}H_{14}$	10	464		
Phenyl nitrite, . . .	$C_6H_5NO_2$		463		
	$C_8H_{12}O^iO^{ii}$	11	461		
Diethyl acetal, . . .	$CH_3CH(O^iC_2H_5)_2$	10	456		
Terpene, . . .	$C_{10}H_{16}$	10	450		
Benzyl chloride, . . .	C_7H_7Cl		445		
Carvol, . . .	$C_{10}H_{14}O$	12?	0.444	0.435	2.28
Phenyl chloride, . . .	C_7H_5Cl		440		
Phenyl thiocyanate, . . .	C_6H_5CNS				
	$C_7H_{14}O^iO^{ii}$	12	434		
Resorcin, . . .	$C_6H_2(O^iHCH_3)_2$	12	431		
Autobutyric anhydride, . . .	$C_2H_3O^iC_4H_7$	12	431		
Cuminol, . . .	$C_{10}H_{12}O^{ii}$	13	0.422	0.414	2.29
Methyl benzoate, . . .	$C_6H_5CO^iO^{ii}CH_3$	13	417		
	C_7H_7Cl		417		
Ethylene chloride, . . .	$C_2H_4Cl_2$		412		
	$C_8H_{16}O^iO^{ii}$	13	402		
Propylene chloride, . . .	$C_3H_6Cl_2$		390		
Phosphoryl chloride, . . .	$POCl$		388		
Amyl nitrate, . . .	$C_5H_{11}NO_3$		388		
Ethyl benzoate, . . .	$C_6H_5CO^iO^{ii}C_2H_5$	14	0.387	0.387	2.25
Paraldehyde, . . .	$C_6H_{12}O_3^{ii}$	15	379	0.379	2.31
Benzoyl chloride, . . .	$C_6H_5CO^{ii}Cl$		373	0.365	2.32
Ethyl oxalate, . . .	$(C_2H_5)_2C_2O^iO^{ii}_2$	16	365		
	CO^iO^{ii}				
	$C_6H_5O^iH < (CH_3)_2$		362		
Methyl paracresolate, . . .	$C_2H_3ClO^iO^{ii}C_2H_5$		359		
Ethyl monochloracetate, . . .	$C_6H_5CHCl_2$		357		
Benzylidene chloride, . . .	$PSCl$		356		
Phosphorus sulphorechloride, . . .	$CH_2ClCHCl_2$				
Trichlorethane, . . .					

From all these we get as a very fair average result,—

$$kAn^{\frac{2}{3}} = 2.28.$$

Sutherland gave the values of kA for some nineteen other substances ; these are given in the following table with the values of n calculated by the help of the preceding equation. The results indicate that Sutherland's equation is of only a comparatively limited application. The values of n can only be roughly approximate ones.

Substance.	kA .	n .
Br_2	0.104	103
$\text{C}_2\text{H}_5\text{Br}$,	259	26
$\text{C}_3\text{H}_7\text{Br}$,	269	25
$i\text{-C}_3\text{H}_7\text{Br}$,	270	25
$\text{C}_8\text{H}_5\text{Br}$,	269	25
$\text{C}_4\text{H}_9\text{Br}$,	271	24
$\text{C}_5\text{H}_{11}\text{Br}$,	270	25
$\text{C}_6\text{H}_5\text{Br}$,	247	28
$\text{C}_7\text{H}_7\text{Br}$,	247	28
$\text{C}_2\text{H}_4\text{Br}_2$,	149	60
$\text{C}_3\text{H}_6\text{Br}_2$,	149	60
CH_3I ,	150	59
$\text{C}_2\text{H}_5\text{I}$,	159	54
$\text{C}_3\text{H}_7\text{I}$,	171	48
$i\text{-C}_3\text{H}_7\text{I}$,	170	49
$\text{C}_3\text{H}_5\text{I}$,	170	49
$\text{C}_4\text{H}_9\text{I}$,	176	47
$\text{C}_5\text{H}_{11}\text{I}$,	178	46
$\text{C}_6\text{H}_5\text{I}$,	168	51

TABLE LXXI.—Surface Tension of Solids.

From the experimental results obtained by Karmarsch, Quincke calculated the following values for the surface tension of the various metals and alloys :—

Substance.	Values of α in 10^8 mgms.	
	Hard Drawn.	Annealed.
Iron,	5731	1592
Platinum.	3025	2388
Copper,	2388	0
Silver,	2388	478
Gold,	1592	478
Zinc,	557	
Steel,	6685	955
German silver,	6685	1114
Silver (12),	5253	2547
Gold (14 carat),	3661	2228
Brass wire,	2547	1751
„ threads,	1751	637

The order which the metals take in the first column of this table is practically that of their hardness.

TABLE LXXII.—Laplace's Constant, K.

Laplace's expression for the pressure at a point in the interior of a liquid is

$$\text{Pressure} = K + \frac{H}{2} \left(\frac{1}{R} + \frac{1}{R_1} \right),$$

where $H/2 = \alpha$ = surface tension ;

R and R_1 are the principal radii of curvature of the liquid surface ;

K = a pressure depending on the nature of the liquid, and always of a very considerable magnitude.

Laplace called K the “intrinsic pressure” ; others have called it the “cohesion pressure,” or the tensile strength of the absolutely pure liquid. It is virtually the same as α/v^2 in the equation of van der Waals. Dupré has given another interpretation of the magnitude K ; it is the measure of the work required for removing a unit volume of the liquid and distributing its molecules in space so that they can no longer exert any attraction on one another. In short, K = work done in vaporising a unit volume of liquid. Thus the work done in vaporising 1 cm.³ of water at 0° C. is 25206 mg.-ergs under a pressure of 1 atmosphere or 1013793 dynes per cm.², so K for water at 0° C. works out as 24,860 atmospheres. From the total heat of vaporisation we can calculate the value of K for any other liquid. The values obtained in this way, it will be seen, differ considerably from those calculated from van der Waal's equation.

Van der Waal's values for K at 0° C.

Ether,	1300	to	1430	atmospheres.
Alcohol,	2100	„	2400	„
Carbon disulphide,	2900	„	2890	„
Water,	10500	„	10700	„
Ethyl chloride,	2040			„
Sulphur dioxide,	3060			„
Carbon dioxide,	2820			„
Methyl acetate,	2225			„
Diethyl amine,	1500			„

For seven of these we have sufficient data to calculate the approximate value of K from the latent heat, etc., at 0° C., and we get—

	Value of K.
Ether,	2880 atmospheres.
Alcohol,	7680 „
Carbon disulphide,	4820 „
Water,	24860 „
Sulphur dioxide,	5450 „
Carbon dioxide,	2220 „
Methyl acetate,	4540 „

It is evident the two methods of calculation must refer to totally different magnitudes.

If a particle fairly within a liquid—*i.e.* further from the surface than the range of molecular action—move towards the surface with a velocity u , it is evident that it cannot cross that surface and escape from the liquid, unless

$$u^2 > 4K/\sigma.$$

TABLE LXXIIc.—*continued.*
 34—IV. Specific Gravity, etc., of Sulphuric Acid—*continued.*

Specific Gravity $\frac{15^{\circ}}{4^{\circ}}$ in vacuo.	Degrees Baumé.	Degrees Twaddell.	100 parts by weight contain		Kilogrammes per Litre.		Pounds per Foot Cube.			Pounds per Gallon.		
			SO ₃	H ₂ SO ₄	SO ₃	H ₂ SO ₄	Total.	SO ₃	H ₂ SO ₄	Total.	SO ₃	H ₂ SO ₄

TABLE LXXIIc.—*continued*.38. Percentage of SO_3 in Nordhausen Oil of Vitriol.

Percentage of free SO_3 = (Percentage found by Titrating - 81.6326) \times 5.4444 ; or,
 more accurately (Percentage found by Titrating - 81.6306) \times 5.4438.

Found by Titrating SO_3 .	Contains per cent.		Found by Titrating SO_3 .	Contains per cent.		Found by Titrating SO_3 .	Contains per cent.	
	H_2SO_4 .	Free SO_3 .		H_2SO_4 .	Free SO_3 .		H_2SO_4 .	Free SO_3 .

Kohlrausch gives for MgSO₄ Solutions at 15° C. :—

5% MgSO₄≡Sp. Gr. 1.0510; 10% MgSO₄≡Sp. Gr. 1.1052; 15% MgSO₄≡1.1602;
 20% MgSO₄≡1.2200; 25% MgSO₄≡1.2861.

155. Specific Gravity, etc., of Aluminium Sulphate Solutions at 15° C. (Gerlach and Reuss.)

Specific Gravity.	Percentage of	
	Al ₂ (SO ₄) ₃ .	Al ₂ (SO ₄) ₃ + 18H ₂ O.
0.569	5	9.737
1.075	10	19.474
1.105	10.282	20
1.574	15	29.211
1.710	15.423	30
2.074	20	38.948
2.355	20.564	40
2.572	25	48.685
3.050	25.705	50

156. Specific Gravity, etc., of Aluminium Sulphate Solutions at various Temperatures. (Reuss.)

Pct. of Al ₂ (SO ₄) ₃ .	Specific Gravity at			
	15° C.	25° C.	35° C.	45° C.
5	1.0569	1.0503	1.045	1.0356
10	1.071	1.022	0.96	0.85
15	1.574	1.522	1.46	1.346
20	2.074	2.004	1.92	1.801
25	2.572	2.483	2.407	2.295

TABLE LXXIIc.—*continued*.

157. Specific Gravity, etc., of Aluminium Sulphate Solutions at 15° C. (E. Larsson.)
 • (Alum-maker's Table.)

TABLE LXXII_E.—Solutions in Aqueous Ethyl Alcohol.

1. Schiff obtained the following values for the weights of various substances dissolved by 100 grammes of dilute alcohol at 15° C. :—

Specific Gravity of Solution at 15°.	Weight of Alcohol in 100 grms. Solution	Substances.										
		NaCl.	KCl.	BaCl ₂ +2H ₂ O.	NaNO ₃	KNO ₃	Na ₂ SO ₄ +10H ₂ O.	K ₂ SO ₄	MgSO ₄ +7H ₂ O.	MnSO ₄ +4H ₂ O.	CuSO ₄ +5H ₂ O.	ZnSO ₄ +7H ₂ O.
0.986	10	28.5	24.7	31.1	65.3	15.2	16.8	4.1	64.7	105.8	15.3	104.3
972	20	22.5	17.2	21.9	48.8	9.3	5.9	1.48	27.1		3.2	64.0
958	30	17.5	12.0	14.7	35.5	5.9		0.55				
939	40	13.2	8.3	10.2	25.8	4.5	1.3	0.21	1.65		0.25	3.6
917	50	9.8	5.3			2.9				2.04		
895	60	5.9	2.9	3.5	11.4	1.7				0.66		
847	80	1.2	0.45	0.5	2.7	0.4						

TABLE LXXII.—*continued.*

2. Gerardin obtained the following results:—

(S = Weight of substance dissolved in 100 parts by weight of the alcoholic solvent).

Specific Gravity at 0°.	Percentage of C ₂ H ₅ OH		For KCl.		For BaCl ₂ .	
	By Volume.	By Weight.	Range.	S.	Range.	S
0.9904	7	5.2	0°–52°	23.2 + 0.27 <i>t</i>	14°–60°	25.1 + 0.246 <i>t</i>
9848	12	9.8	4 –60	19.9 + 0.255 <i>t</i>	14 –63	21.6 + 0.225 <i>t</i>
9793	19	15.4	4 –43	15.7 + 0.233 <i>t</i>	11 –45	17.3 + 0.206 <i>t</i>
9726	28	23	3 –34	11.9 + 0.205 <i>t</i>	15 –50	13.0 + 0.181 <i>t</i>
9573	42	35	10 –60	7.1 + 0.162 <i>t</i>	13 –50	8.18 + 0.139 <i>t</i>
9390	53	45	2 –57	4.2 + 0.125 <i>t</i>	12 –47	5.11 + 0.105 <i>t</i>
8967	72	65	12 –65	1.89 + 0.061 <i>t</i>	12 –47	2.38 + 0.051 <i>t</i>

3. For the values of S at 18° the same investigator obtained the following:—

Specific Gravity at 0°.	Percentage of C ₂ H ₅ OH		Values of S for		
	By Volume.	By Weight.	SrCl ₂ .	KI.	NaC ₂ H ₃ O ₂ .
0.9904	7	5.2	49.8	130.5	38.0
9848	12	9.8	47.0	119.4	35.9
9726	28	23	39.6	100.1	29.8
9665	35	29	35.9	89.9	27.5
9528	45	38	30.4	76.9	23.5
9390	53	45	26.8	66.4	20.4
9088	67	59	19.2	48.2	14.6
8464	90	86	4.9	11.4	3.9
8322	94	91	3.2	6.2	2.1

4. Employing alcohol of Specific Gravity 0.9390, he obtained the following values for S:—

<i>t</i> ° C.	NH ₄ Cl.	K ₂ SO ₄ .	Pb(NO ₃) .
4°	11.2	0.16	4.96
8	12.6	0.21	5.82
22			8.77
27	19.4		
38	23.6		
40			12.8
50			14.9
56	30.1		
60		0.92	

TABLE LXXII.—*continued.*

TABLE LXXII. 23.—*continued.*

NOTES.

- (a) Saturated KNO_3 + aq. treated with NH_4Cl .
 (b) Saturated NH_4Cl + aq. treated with KNO_3 .
 (c) Simultaneous treatment of NH_4Cl and KNO_3 .
 (d) By warming solution containing excess of both salts, and cooling to $14^{\circ}\text{--}8^{\circ}\text{C}$.
 (e) Saturated $\text{Ba}(\text{NO}_3)_2$ + aq. treated with NH_4Cl .
 (f) Saturated NH_4Cl + aq. treated with $\text{Ba}(\text{NO}_3)_2$.
 (g) Simultaneous treatment of NH_4Cl and $\text{Ba}(\text{NO}_3)_2$.
 (h) Saturated K_2SO_4 + aq. treated with NH_4Cl .
 (i) Saturated NH_4Cl + aq. treated with K_2SO_4 .
 (j) Simultaneous treatment of NH_4Cl and K_2SO_4 .
 (k) Weights dissolved in 100 parts of water.
 (l) 100 parts water saturated with NH_4Cl at 10° , and then with Na_2SO_4 at 11°C .
 (m) 100 parts water saturated with Na_2SO_4 at 10° , and then with NH_4Cl at 11°C .
 (n) Saturated NaCl + aq. treated with NaNO_3 .
 (o) Saturated NaNO_3 + aq. treated with NaCl .
 (p) Simultaneous treatment of NaCl and NaNO_3 .
 (q) By warming solution containing excess of both salts, and cooling to 20°C .
 (r) Saturated NaCl + aq. treated with KNO_3 .
 (s) Saturated KNO_3 + aq. treated with NaCl .
 (t) Simultaneous treatment of NaCl and KNO_3 .
 (u) Solubility of anhydrous Na_2CO_3 in 100 parts NaCl + aq. containing % NaCl .
 (v) Amounts dissolved in 100 parts of water when $\text{Na}_2\text{CO}_3 + 10\text{H}_2\text{O}$ is in excess.
 (w) By warming solution containing excess of both salts, and cooling to 14°C .
 (x) Saturated KCl + aq. treated with K_2SO_4 .
 (y) Simultaneous treatment of KCl and K_2SO_4 .
 (z) Saturated K_2SO_4 + aq. treated with KCl .
 (α_1) 100 parts water saturated at 11° with NH_4NO_3 , then at 9° with KNO_3 .
 (β_1) 100 parts water saturated at 11° with NH_4NO_3 , then at 15° with KNO_3 .
 (c_1) Saturated KNO_3 + aq. treated with NaNO_3 .
 (α_2) Saturated NaNO_3 + aq. treated with KNO_3 .
 (e_1) }
 (f_1) } Weights dissolved in 100 parts water.
 (g_1) }
 (h_1) Saturated KNO_3 + aq. treated with $\text{Ba}(\text{NO}_3)_2$.
 (i_1) Saturated $\text{Ba}(\text{NO}_3)_2$ + aq. treated with KNO_3 .
 (j_1) }
 (k_1) } Simultaneous treatment of KNO_3 and $\text{Ba}(\text{NO}_3)_2$.
 (l_1) }
 (m_1) } Na_2SO_4 in excess, and given amount of CuSO_4 added.
 (n_1) }
 (o_1) Both in excess.
 (p_1) }
 (q_1) } CuSO_4 in excess, and Na_2SO_4 added.
 (r_1) }
 (s_1) }
 (t_1) } MgSO_4 in excess, and given amount of CuSO_4 added.
 (u_1) }
 (v_1) Both in excess.
 (w_1) }
 (x_1) } CuSO_4 in excess, and MgSO_4 added.
 (y_1) }

TABLE LXXII.—*continued.*

24. For the three salts, $\text{NaCl} + \text{KCl} + \text{K}_2\text{SO}_4$, Precht and Wittgen obtained the following results:—

100 parts of water at $t^\circ \text{C.}$ dissolve			
$^\circ \text{C.}$	Parts NaCl.	Parts KCl.	Parts $\text{K}_2\text{SO}_4.$
10°	33.43	3.18	8.10
20	34.01	3.06	8.90
30	34.56	2.95	9.56
40	35.16	2.81	10.38
50	35.77	2.84	11.07
60	36.40	2.72	11.93
70	36.64	3.20	12.82
80	36.04	5.06	12.26
90	35.86	6.98	12.42
100	35.63	8.79	12.56

25. Solubility of $\text{KCl} + \text{NaCl}$ in 20% aqueous Solution of MgCl_2 . (Precht and Wittgen.)

$t^\circ \text{C.}$	Percentage of NaCl.	Percentage of KCl.
10°	5.7	4.2
20	5.8	5.1
30	5.9	6.0
40	6.0	6.9
50	6.1	7.9
60	6.3	8.9
70	6.4	9.9
80	6.6	10.9
90	6.7	11.9
100	6.9	13.0

TABLE LXXII_F.—*continued*.26. Solubility of Mixtures of NaNO_3 and KNO_3 . (Carnelley and Thomson.)

Percentage NaNO_3 in Mixture before Solution.	Weight of Mixture dissolved in 100 parts Water at 20° C.	Parts NaNO_3 dissolved.	Parts KNO_3 dissolved.	Percentage NaNO_3 in Residue after evaporating Solu- tion to Dryness.
100	86.8	86.8	0	100

	Weight of Water to be added to 100 parts of Substance.	Percentage of Sub- stance in Solution.		Weight of Water to be added to 100 parts of Substance.	Percentage of Sub- stance in Solution.		Weight of Water to be added to 100 parts of Substance.	Percentage of Sub- stance in Solution.		Weight of Water to be added to 100 parts of Substance.	Percentage of Sub- stance in Solution.

The use of the preceding table is self-evident. Thus, if it is required to make a solution containing 52 per cent. of any soluble substance by looking for 52 in the first column, we find from the second column that we must add 108.3333 grammes of the substance to 100 grammes of water; or, by looking for 52 in the third column, we find from column 2 that we should have to add 92.3077 grammes of water to 100 grammes of the substance.

If P = percentage of substance in the stronger of two solutions,
 and p = " " " " weaker " "
 \therefore weight of water that must be added to 1 unit weight of the stronger to produce the weaker = $\frac{P}{p} - 1$; and weight of substance which must be added to 1 unit weight of the weaker to bring it up to the higher strength = $\frac{100 - p}{100 - P} - 1$.

For example, a solution of sulphuric acid of 55 degrees Baumé contains 70 per cent. of H_2SO_4 , how much water must be added to every gramme of such solution to reduce it to 31 degrees Baumé contained in 36 per cent. H_2SO_4 ?

$$\text{Here } \frac{P}{p} - 1 = \frac{70}{36} - 1 = 0.94 \text{ gramme.}$$

In 1 gramme of 70 per cent. solution we have .7 gramme of H_2SO_4 ,

$$\therefore \text{Percentage of } H_2SO_4 \text{ in diluted solution} = \frac{0.7 \times 100}{1 + 0.94} = 36.$$

As there is, in nearly every instance, a change in the total volume when two liquids of different densities or constitutions are mixed together, no simple formula can be given for diluting or fortifying volumetrically a solution of any given density to produce another of a required density: where the percentage of substance held in solution in each case is known, as well as the densities, then the calculation can be easily made.

If P , D , and V represent respectively the percentage contents, density, and volume of a comparatively strong solution; p , d , and v , the corresponding values for a weaker one; and p , d , and v , those obtained by mixing V c.cms. of the first and v c.cms. of the second.

$$\text{Then, if } v=1, \text{ we get } V = \frac{d(p-p)}{D(P-p)}; \text{ or } v=1 \text{ litre } \therefore V = 1000 \cdot \frac{d(p-p)}{D(P-p)} \text{ c.cms.} \quad (1)$$

$$\text{And if } V=1 \therefore v = \frac{D(P-p)}{d(p-p)}; \text{ or } V=1 \text{ litre } \therefore v = 1000 \frac{D(P-p)}{d(p-p)} \quad \dots \dots \dots (2)$$

$$\text{And, finally, if } v=1 \therefore V = \frac{d \cdot p - p}{D \cdot P - p}; \text{ and } v = \frac{d \cdot P - p}{d \cdot P - p};$$

$$\text{or } v=1 \text{ litre } \therefore V = 1000 \cdot \frac{d \cdot p - p}{D \cdot P - p} \text{ c.cms., and } v = 1000 \frac{d \cdot P - p}{d \cdot P - p} \text{ c.cms.} \quad \dots (3)$$

Should p become 0, i.e. if the second liquid be water ($d=1$), then equation (1) becomes—

$$V = \frac{p}{D(P-p)}; \text{ and for } v=1 \text{ litre, } V = \frac{1000p}{D(P-p)} \text{ c.cms.} \quad \dots \dots (4)$$

$$(2) \text{ becomes } v = \frac{D(P-p)}{p}; \text{ and for } V=1 \text{ litre, } v = \frac{1000D(P-p)}{p} \quad \dots (5)$$

$$\text{and } (3) \text{ for } v=1 \text{ litre gives } V = 1000 \cdot \frac{dp}{DP} \text{ c.cms., and } v = 1000 \cdot \frac{d(P-p)}{P} \text{ c.cms.} \quad \dots (6)$$

For example, if we required to know in what proportions solutions of sulphuric acid of density = 1·4, percentage $\text{H}_2\text{SO}_4 = 50\cdot11$, and density = 1·1, percentage of $\text{H}_2\text{SO}_4 = 14\cdot35$, respectively, must be mixed to make up a litre of density 1·3 and percentage $\text{H}_2\text{SO}_4 = 39\cdot19$, we get by equation (3)—

$$V = 1000 \cdot \frac{1\cdot3 \cdot 39\cdot19 - 14\cdot35}{1\cdot4 \cdot 50\cdot11 - 14\cdot35} = 645\cdot006 \text{ c.cms.}$$

$$v = 1000 \cdot \frac{1\cdot3 \cdot 50\cdot11 - 39\cdot19}{1\cdot1 \cdot 50\cdot11 - 14\cdot35} = 360\cdot891 \text{ c.cms.}$$

Weight of H_2SO_4 in $V = 645\cdot006 \times 1\cdot4 \times 0\cdot5011 = 452\cdot498$ grms.

„ „ „ $v = 360\cdot891 \times 1\cdot1 \times 0\cdot1435 = 56\cdot967$ „

Total = 509·465 grms.

Weight of H_2SO_4 in 1 litre of 1·3 density = $1000 \times 1\cdot3 \times 0\cdot3919 = 509\cdot467$ „

If we desired to find the weights (W and w) of the strong and weak solutions which must be put together to make up 1 litre of the medium, we get—

$$\left. \begin{aligned} W &= 1000d \cdot \frac{P-p}{P-p} \text{ grms.} \\ \text{and } w &= 1000d \cdot \frac{P-p}{P-p} \text{ grms.} \end{aligned} \right\} \dots (7)$$

and when $p=0$, (7) becomes—

$$\left. \begin{aligned} W &= 1000d \frac{P}{P} \\ w &= 1000d \cdot \frac{P-p}{P} \end{aligned} \right\} \dots (8)$$

The volume and density of a mixture of solutions can only be ascertained by experiment or by reference to tables giving the results of actual trials.

TABLE LXXIIH.—Relations of Solubility to Pressure, Temperature, etc.

Sorby, investigating the influence of pressure on solubility, obtained the following results:—

Substance.	<i>a</i>	<i>b</i>	<i>c</i>	<i>d</i>
Ammonium chloride,	20	164	-1·045	-0·638
Sodium chloride,	13·57	97	+0·407	+0·419
Copper sulphate,	4·83	60	1·91	3·183
Potassium ferricyanide,	2·51	86	0·288	0·395
Potassium sulphate,	31·21	63	1·84	2·914
Potassium ferrocyanide,	8·90	66	1·64	2·845

TABLE LXXIIH.—*continued*.

a = Increase of volume of salt in crystallising out of saturated solution, expressed in percentages of the solid salt.

b = Pressure in atmospheres.

c = Percentage increase of solubility under pressures given in b (originally dissolved salt = 100).

d = Corresponding increments under pressure of 100 atmospheres.

From these he deduces the expression :—

$$S_p = S_o + \frac{pc}{m},$$

where m is a function of the mechanical equivalent of the force of crystallisation.

K. Möller obtained the following values for the amount of salt dissolved in 100 parts of water under various pressures and at various temperatures :—

(1) Sodium Chloride.

p in atmos.	$t^\circ = 0^\circ$	9°	15°	20°	25°	30°
1	35.59	35.72	35.70	35.78	35.81	36.01
20	35.79	35.84	35.84	35.82	35.99	36.10
40	35.95		35.87			

(1a) Sodium Sulphate.

p	$t = 0^\circ$	15°
1	4.60	12.76
20	4.74	11.88
30		11.77
40		11.53

(1b) Potassium Sulphate.

p	$t = 0^\circ$	$15^\circ.5$	$16^\circ.2$
1	7.31	10.19	10.32
20	7.68	10.43	10.54
30	7.69		

TABLE LXXIIH. (2).

The expressions for the relations between solubility and temperature are practically all empirical. In the following, S_t = weight of substance dissolved in 100 grammes of water at temperature t° :—

Substance.	Range of Temp.	S_t	Authority.
NH ₄ Cl,	0° to 100°	$29.7 + 0.35t + 0.00125t^2$	
	100 - 116	$29.7 + 0.3218t + 0.001542t^2$

In alcohol S_t = weight of salt in 100 parts alcohol.

NH₄Cl, 0°-56° $9.80 + 0.351t + 0.00024t^2$ (Sp. Gr. of Alcohol 0.939)

If c denote the weight of alcohol contained in 100 parts of an aqueous solution of alcohol, then the weight of BaCl₂ dissolved by 100 parts of such solution will be

$$30.25 - 0.7021c + 0.00479c^2 - 0.0583c^3.$$

TABLE LXXIIH. (4).

Nordenskjöld gives :—

$$dS = bSdt, \text{ or } \frac{dS}{S} = bdt;$$

and therefore,

$$\text{Log}_e S_t = bt + a,$$

where a and b are constants. A more satisfactory form is

$$\text{Log}_e S_t = a + bt + ct^2.$$

The values of the constants are given as follows for the undermentioned salts :—

Substance.	a	b	c
NH_4Cl	-0.5272	+0.5483	-0.1732

β = Absorption coefficient = volume of gas (reduced to st. temp. and pressure) absorbed by 1 litre of water when pressure of gas outside liquid is 760 mm.

β_1 = Solubility of gas = volume of gas (corrected as above) absorbed by 1 litre when total pressure is 760 mm. $\beta = \beta_1 \frac{760 - p}{760}$; p = tension of aqueous vapour at t .

* Calculated from nitrogen and oxygen.

TABLE LXXIII_B.—Coefficients of Absorption of Gases in Water.

ϵ , the volume of gas corrected to 0° C. and 760 mms. pressure absorbed by each unit volume of water at temperatures between 0° and 40° C., the pressure of the dry gas outside the water during absorption being 760 mms.

130	676	300	738	700	817		

(10) Solubility of SO_2 in Water under various Pressures. (Sims.)

P = Partial pressure in mms.

w = Weight in grms. of SO_2 exerting pressure P, dissolved in 1 grm. weight of water.

W = Calculated weight of SO_2 absorbed under 760 mms. pressure if absorption were exactly proportional to pressure.

v = Volume of w grms. of SO_2 at 0°C. under pressure of 760 mms.

V = " W " " " "

TABLE LXXIII_F.—Formulæ, etc., referring to the Absorption of Gases.

Henry's Law.—“*The mass of gas absorbed by a specified mass of a liquid varies directly as the pressure exerted by the gas*”; or “*A given mass of a liquid absorbs, under all pressures, the same volume of a gas.*”

β = Coefficient of absorption of a gas.

v = Volume in cm.³ of gas absorbed by V cm.³ of liquid at temperature t° C.

α = Coefficient of gaseous expansion.

$$\beta = \frac{v}{V(1 + \alpha t)}.$$

$$\beta_t = \beta_0 + \alpha t + b t^2 + c t^3.$$

If by τ we denote any other temperature, we may write

$$\beta_t = \beta_\tau + \alpha(t - \tau) + b(t - \tau)^2 + c(t - \tau)^3,$$

where, of course, the values of α , b , and c are different from the corresponding values in the preceding equation.

One volume of saturated aqueous solution between 0° C. and 20° contains (68.861 - 1.87025*t* + 0.01225*t*²) volumes of SO₂, and between 21° and 40° (60.952 - 1.38898*t* + 0.00726*t*²) volumes of SO₂.

Winkler found the following expression very approximately true in the case of water and the gases H_2 , N_2 , CO , NO , and O_2 :—

$$\beta_\tau = \beta_t \left(1 - \frac{\mu_t - \mu_\tau}{\mu_t} \sqrt[3]{\frac{m}{M}} \right) = \beta_t \left(1 - \frac{\mu_t - \mu_\tau}{\mu_t} \cdot \frac{\sqrt[3]{m}}{k} \right),$$

where β_τ, β_t = coefficient of absorption of the gas at τ° and t° respectively,
 μ_τ, μ_t = internal friction of the absorbed gas at τ° and t° „
 m = molecular weight of gas,
 M = molecular weight of the solvent,
 k = A constant = $\sqrt[3]{M}$.

Calculating the value of k from experimental results he gets for—

H_2 in water	$k = 3.604$	NO in water	$k = 3.759$
N_2 „	$= 3.880$	O_2 „	$= 3.810$
CO „	$= 3.872$	Mean „	$= 3.785$

Supposing that the molecule of liquid water corresponds to $3H_2O$, he gets :—

$$\sqrt[3]{M} = \sqrt[3]{54} = 3.7798 = k.$$

Taking this value for k , Winkler calculated the values of β at $5^\circ, 10^\circ, 15^\circ, 20^\circ, 25^\circ, 30^\circ, 40^\circ, 50^\circ$, and 60° C. from the value of β at 0° C. by the help of his equation, and found them agree very closely with his experimental results. The deviation shows a decided tendency to increase with the rise of temperature; and in every case except that of hydrogen, it is in the direction that the equation indicates if we admit that the molecules of liquid water tend to become less complex as the temperature rises—*i.e.* the mean value of $\sqrt[3]{M}$ diminishes as dissociation proceeds. Possibly there will be also some change in the mean value of m as the temperature varies.

TABLE LXXIV.—Molecular Weights.

I. According to Avogadro's Law we have in case of gaseous bodies—

$$M_A : M_B = D_A : D_B$$

and the calculation of Molecular Weights from Vapour Densities has been explained in section LXI.

II. "Cryoscopic or Lowering of Freezing Point" Method. (Raoult's, Beckmann's)—

Let d = Number of degrees the freezing point of the solvent is lowered when

p = Grammes of substance dissolved in 100 grms. of solvent,

E = Constant to be determined for each special solvent = Number of degrees the freezing point of the solvent would be lowered if a gramme-molecule of the substance were dissolved in 100 grms. of the solvent,
= "Molecular Depression" for that special solvent,

$$\therefore M = E \frac{p}{d};$$

or, putting S = Weight of solvent used,

s = Weight of substance in solution,

$$M = 100E \cdot \frac{s}{Sd}.$$

E can be determined experimentally for each solvent by noticing the value of d when known weights of substances of known molecular weights are dissolved in a known weight of the solvent, or it may be calculated for any substance whose freezing point and latent heat of liquefaction are known. The researches of Pfeffer, van't Hoff, etc., have shown that in fairly dilute solutions "Dissolved substances exert, in the form of osmotic pressures, the same pressure as they would exert at the same temperature as gases occupying the same space as their solutions occupy, and this osmotic pressure is directly proportional to the absolute temperature":—that is, for substances in dilute solutions, as well as for substances in the gaseous state,—

$$PV = KT,$$

where V is the molecular volume, and K a constant virtually independent of the nature of the dissolved substance, and the same as for gaseous substances.

If with N molecules of a solvent, whose freezing point is T , we associate n molecules of a foreign substance, and cool it down to $(T-d)$ until the solvent begins to solidify, and allow as much of it to solidify as was associated with one molecule of the foreign substance, we shall lose osmotic pressure, P , through the volume, V , of $\frac{N}{n}$ molecules of the solvent—i.e., PV units of work. If \mathfrak{L} represent the molecular latent heat of the

Gaseous molecules under a very slight pressure tend to dissociate; while, when subjected to a very great pressure, several comparatively simple molecules often coalesce to form more complex ones. It also happens similarly with solutions: in very dilute ones our calculated molecular weights may come out too low, and in concentrated ones they are certain to be much too high—i.e., in dilute solutions the "Specific Depression" $\frac{d}{p}$ is likely to be abnormally high, while in concentrated solutions it is most likely to be abnormally low. Thus, with 100 grms. benzol (E=49) 0.164 grm. of ethyl alcohol caused a depression = 0°·175, giving

$$\mathfrak{M} = 49 \times \frac{164}{175} = 45.9.$$

With the same weight of solvent 32.45 grms. of the alcohol caused a depression = 5°, giving

$$\mathfrak{M} = 49 \times \frac{32.45}{5} = 318.$$

The vapour density gives C₂H₅OH as the molecular formula and \mathfrak{M} = 46.

TABLE LXXIVB.

It must also be borne in mind that substances may form complex molecules with some of the solvent—thus, calcium chloride in aqueous solution seems to exist as $\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$ rather than CaCl_2 , and in neither case will the experimental result for E agree with the calculated one.

CaCl_2		d	$\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$	
$\frac{d}{p}$	p		p	$\frac{d}{p}$
0.40	1	0.4	1.99	0.201
45	2	0.9	4.02	223
463	4	1.85	8.21	225
475	6	2.85	12.57	226
488	8	3.9	17.20	226
490	10	4.9	21.80	224
528	14	7.4	31.89	232
555	18	10.0	43.05	231

The last two results seem to indicate a more complex hydrate than $\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$, and we have frequent indications that the degree of hydration differs in solutions of different strengths. Thus, with sodium chloride the results up to 14 grms. NaCl to 100 grms. of water seem to indicate molecules of NaCl, and above that strength of $\text{NaCl} \cdot 2\text{H}_2\text{O}$.

NaCl		d	$\text{NaCl} \cdot 2\text{H}_2\text{O}$

Where the values of E are much higher than the calculated magnitude, it is quite evident that dissociation or ionisation must have taken place; and where the values are too low, polymerisation must have occurred.

III. Vapour Tension, and “Ebullistic or Boiling Point” Method. (Beckmann's, etc.)

Arrhenius' Law: “The rise (dT) of the boiling point (T) of a solvent, caused by dissolving n gramme-molecules of a comparatively non-volatile substance in 100 grms. of the solvent, is directly proportional to n and the square of T ; and indirectly proportional to λ , the latent heat of vaporisation of 1 gram. of the solvent.”

From this it follows that the formula

$$\Delta T = E \cdot \frac{p}{d}$$

is applicable also when d = Change of boiling temperature when p grammes of a substance are dissolved in 100 grms. of the solvent.

Also,
$$E = \frac{0.02T^2}{\lambda},$$

where T = Boiling temperature on absolute scale,

λ = Latent heat of vaporisation of 1 gram. of solvent at T° .

This law can be deduced from thermodynamical principles, but the full investigation would be out of place here, and we can only give such equations and tables as are likely to be useful in actual experimental work.

If Π denote the vapour pressure of the pure solvent at temperature T ,
 Π_1 „ „ „ of a solution of a fairly non-volatile substance in such a solvent, then,—

$\frac{\Pi - \Pi_1}{\Pi}$ = a constant for same degree of concentration, and the value of such constant is quite independent of the temperature as long as the solution is dilute, and as long as the vapour pressure of the dissolved substance is an infinitesimally small quantity compared with that of the solvent at the same temperature. This law can be deduced from thermodynamical principles, and it has also been established experimentally.

If n represent the number of molecules of the dissolved substance associated with N molecules of the solvent, we get—

$$\frac{\Pi - \Pi_1}{\Pi} = C \frac{n}{N+n}.$$

The limiting value of C is evidently = 1,

$$\text{consequently we may put } \frac{\Pi - \Pi_1}{\Pi} = \frac{n}{N+n}, \text{ i.e., } \frac{\Pi - \Pi_1}{\Pi_1} = \frac{n}{N}.$$

Employing p and M as in last section,—

$$n = \frac{p}{M}, \text{ and } N = \frac{100}{M}.$$

$$\frac{\Pi - \Pi_1}{\Pi_1} = \frac{Mp}{100M},$$

$$\text{so we get } \dots \dots \dots \frac{M}{M} = \frac{Mp\Pi_1}{100(\Pi - \Pi_1)},$$

$$\text{and } \dots \dots \dots M = \frac{100(\Pi - \Pi_1)M}{p\Pi_1};$$

$$\text{or, if } w = \text{weight dissolved in 1 gramme molecule of solvent, } \frac{M}{M} = \frac{w\Pi_1}{\Pi - \Pi_1}.$$

The great difficulty of measuring minute differences of vapour pressures, and the comparative ease of estimating changes in boiling temperature under constant pressure, has led to the adoption of the "Boiling Point" method in preference to the "Vapour Tension" mode of procedure. In using the Boiling Point method the temperature must be that of the liquid, and not that of the vapour.

In addition to van't Hoff's formula, we have another approximate expression for E (Schiff, Tronter), viz., $E = 0.00096TM$, where M is the molecular weight of the solvent; or, taking more exact values for the constants,

$$E = 0.01976 \frac{T^2}{\lambda} = 0.0009565MT.$$

The equality of the two expressions depends on the equation $\frac{M\lambda}{T} = \text{a constant} = 20.658$ very nearly, and for a large number of solvents.

The following table includes nearly all liquids whose boiling points under 760 mms. pressure, and latent heats of vaporisation, are known.

TABLE LXXIV_D.

" acetate,	CH ₃ COOH	60	118	84.9	35.58	22.44	13.03
" butyrate,	C ₃ H ₇ COOH	88	164	114	33.10	36.78	22.96
" valerate,	C ₄ H ₉ COOH	102	184	103.52	41.75	44.58	23.10
Acetic anhydride,	(C ₂ H ₃ O) ₂ O	102	137	66.1	50.25	40.00	16.44
Methyl formate,	HCOOCH ₃	60	32.9	117.1	15.79	17.65	22.96
Acetone,	CH ₃ COCH ₃	58	56.6	125.8	17.13	18.29	22.45

It rarely happens that anything stronger than a 1 per cent. solution gives reliable results, and the vapour tension of the dissolved substance at the boiling temperature of the solvent should be very slight.

Ostwald gives the following values for—

	100 E.		100 E.
Water,	520	Ethyl acetate,	2610
Ethyl alcohol,	1150	Benzol,	2670
Acetone,	1670	Phenol,	3040
Ethyl ether,	2110	Aniline,	3220
Carbon disulphide,	2370	Chloroform,	3660
Hydrogen acetate,	2530	Ethylene bromide,	6320

These are identical with the values given by Beckmann, *Zeitschr. f. physik. Chem.*, iv. 533, etc.

The variation of the atmospheric pressure complicates this method very largely, and, whenever available, the freezing point method is to be preferred.

The following table, arranged from G. Tammann's investigations, is very suggestive as to the effect of higher concentration on the vapour pressure of aqueous solutions.

TABLE LXXIV_B.

Diminution of Vapour Pressure of Water at 100° C. caused by dissolving n grammes molecules of various salts in 1 kilogramme of water; diminution of pressure given in millimetres of ice-cold mercury.

TABLE LXXIVF.

Prof. Ramsay, from observations on the diminution of vapour pressure of mercury, obtained the following results for the various metals:—

	Molecular Weight calculated.	Atomic Weight O=16.		Molecular Weight calculated.	Atomic Weight O=16.
Li	7.1	7.03	Al	33.1 - 36.7	27.1
Na	21.6 - 15.1	23.05	Ga	69.7	70
K	30.2 - 29.1	39.15	Sb	136 - 301	120.2
Mg	24.0 - 21.5	24.36	Tl	197.6 - 163.6	204.1
Ca	19.1	40.1	Bi	214 - 232	208.5
Ba	75.7	137.4	Sn	117.4 - 149.5	119.0
Mn	55.5	55.0	Pb	200 - 250	206.9
Zn	65.4 - 70.1	65.4	Ag	112.4	107.93
Cd	103.8 - 99.7	112.4	Au	207.4 - 208.1	197.2

The approximations, though not very close, indicate very emphatically that metals in mercurial solution tend to form monatomic molecules.

IV. Distillation of Mixed Liquids.

If a mixture of two liquids distils over at temperature T in proportion of $Q_1 : Q_2$, and if the vapour pressures of the two liquids at T are Π_1 and Π_2 respectively, and if d_1 and d_2 be the vapour densities of the two bodies,

$$\therefore Q_1 : Q_2 = \Pi_1 d_1 : \Pi_2 d_2. \quad (\text{Gay-Lussac, Wanklyn, Berthelot, etc.})$$

Now, if the molecular weight of one (M_1) be known, that of the other can be easily calculated from Naumann's formula—

$$M = \frac{M_1 \cdot Q_2 \Pi_1}{Q_1 \Pi_2}.$$

This formula assumes that the vapour density of each constituent of the mixture is normal at the temperature T , but such is never the case, and the method is at best only roughly approximate, and of more value as a contribution to chemical theory than as a working method. With such liquids as water, benzene, etc., whose vapour pressures are known for various temperatures, the vapour pressure (Π_2) of the other substance may be taken as = Barometric pressure - Π_1 .

Naumann's formula is useful for calculating molecular weights from the results of steam distillations and other analogous operations, but the results are only roughly approximate. Better results may be obtained as follows:—

$$d_2 = \frac{d_1 Q_2 \Pi_1}{Q_1 \Pi_2},$$

where d_1 = density (here either weight of 1 litre, or "vapour density," referred to air or hydrogen) of the substance of known molecular weight at temperature T and under the pressure Π_1 , and d_2 = corresponding value for the second substance under the pressure Π_2 .

For example, taking the data used by Beilstein: In the steam distillation of naphthalin at $98^{\circ}2$ C. (cor.) and barometric pressure of 733 (cor.), the distillate consisted of 49.4 grms. of water and 8.9 grms. of naphthalin.

Here Π = Tension of aqueous vapour at $98^{\circ}2$ C. = 712.27 mms. (Table LIXA),

$\therefore \Pi_2 = 733 - 712.27 = 20.73$.

d_1 = Weight of 1 litre of water vapour at $98^{\circ}2 = 0.57043$ grms. (Table LXVIIA),

$$\therefore d_2 = \frac{0.57043 \times 8.9 \times 712.27}{49.4 \times 20.73}.$$

Correcting to the standard pressure of 1 metre of ice-cold mercury, we get the density the hypothetical vapour of naphthalin at $98^{\circ}2$ C. under 1000 mms. pressure

$$= \frac{0.57043 \times 8.9 \times 1000}{49.4 \times 20.73} = 4.9575.$$

According to Table LXIE. the molecular volume at $98^{\circ}2$ C. is 23.070056, and consequently molecular weight of naphthalin

$$= 4.9575 \times 23.070056 = 114.37;$$

or using Naumann's formula

$$M = \frac{18.016 \times 8.9 \times 712.27}{49.4 \times 20.73} = 111.52.$$

PART IV.—ANALYTICAL CHEMISTRY.

IN the following tables every possible precaution has been taken to ensure the strictest accuracy, and it is hoped that errors which have escaped detection are, at the very worst, few and insignificant. The factors, multiples, logarithms, etc., have been calculated to as many decimal places as the author deemed necessary for the very finest analytical work; for ordinary work, technical and commercial, considerably fewer decimals will suffice.

The values for the atomic weights adopted in the calculation of these tables are those given by the International Committee at the commencement of the year 1904, the standard being $O=16$. As far as the more important elements are concerned, these values are likely to remain unaltered, and only those for the most rare and recently discovered substances are at all likely, at anything like a moderately early date, to undergo any appreciable modifications. As far as the ordinary daily routine of commercial and technical work is concerned, the author ventures to hope that these tables may prove of permanent value.

TABLE LXXV A.—continued.

TABLE LXXVB (1).—Volumetric Analysis.

The first column gives the formula of the substance to be estimated; the second column gives in milligrammes the weight of the substance corresponding to each centimetre cube of decinormal solution; and the third column contains the logarithms of the numbers in column 2.

By taking for assay as many decigrammes as there are mgms. represented in column 2, each c.cm. of $\frac{N}{10}$ solution will correspond to 1 per cent. of the substance whose formula is given in column 1. For example, if one wished to ascertain the percentage of Na_2CO_3 in soda crystals, one would weigh out exactly 5.305 decigrammes, *i.e.*, 0.5305 gm., of the crystals, dissolve this amount in water and neutralise with $\frac{N}{10}$ acid: each c.cm. of acid required will represent 1 per cent. of Na_2CO_3 in the crystals, so that, if it needed 37.8 c.cms. acid, the crystals would contain 37.8 per cent. of Na_2CO_3 . In this way all trouble in calculating out the results of volumetric determinations can be avoided.

This Table B (1) gives all the normal values for precipitation, acidimetry, alkalimetry, oxidation, reduction, and iodometric methods; some slightly abnormal values are given in Table B (2).

Formula of Substance to be estimated.	Weight, in mgms., of Substance \equiv 1 cm. ³ $\frac{N}{10}$ Solution.	Logarithm.

Aluminium—			
Al,	The Al is precipitated by caustic NaOH or KOH solution and a further quantity of the alkali is added until all the precipitate disappears; two titrations are then made with $\frac{N}{10}$ mineral acid, employing methyl orange as indicator in one case and phenolphthalein in the other. The difference between the two titrations corresponds to the Al present: Cross and Bevan find that by this method $4Al \equiv 5SO_4$.	1.084	0.0350293

FeC ₆ N ₆ ''',	Ferrocyanides in very dilute acid solutions	21.214	1.3266226

TABLE LXXVB (3).—continued.

Formula of Substance to be estimated.	Method of Estimation, etc.	Weight in mms. of Substance = 1 c.c. $\frac{N}{10}$ Solution.	Logarithm.
Cyanogen and its deriva-			
tives—			
$H_4FeC_6N_6$	are converted by $KMnO_4$ into ferricyanides.	21.6172	1.8347994
$(NH_4)_4FeC_6N_6 + 3H_2O$	$2H_4FeC_6N_6 + O = 2H_3FeC_6N_6 + H_2O$,	33.8476	1.5295279
$K_4FeC_6N_6 + 3H_2O$	so $O = 2FeC_6N_6'''$.	42.2788	1.6261226
$Na_4FeC_6N_6 + 10H_2O$		48.45	1.6852938
$Fe_3'''(FeC_6N_6)_3'''$		28.6673	1.4573873
FeC_6N_6'''	Ferricyanides in presence of HCl react	21.214	1.3266226
$H_3FeC_6N_6$	with KI thus:	21.5164	1.3327696
$(NH_4)_3FeC_6N_6 + 3H_2O$	$2K_3FeC_6N_6 + 2KI = 2K_4FeC_6N_6 + I_2$,	32.0104	1.5056979
$K_3FeC_6N_6$	so $I = FeC_6N_6'''$.	32.959	1.5179740
$Na_3FeC_6N_6 + H_2O$		29.9306	1.4761154
CNS	Thiocyanates titrated with $KMnO_4$.	0.9683	1.9800247
$HCNS$	$O = \frac{1}{3}CNS$.	0.98513	1.9934950
NH_4CNS		1.26953	0.1036441
$KONS$		1.62083	0.2097383
$NaCNS$		1.3525	0.1311372
$AgCNS$		2.76716	0.4420353
$CuCNS$		2.0283	0.3071393
Organic acids and their			
corresponding com-			
pounds—			
$HCOOH$	By acidimetric methods.	4.6016	0.6629089
$HCOONH_4$	By acidimetric and alkalimetric methods:	6.308	0.7998917
$HCOOK$	distillation, ignition, or precipitation being	8.4158	0.9250954
$HCOONa + H_2O$	sometimes necessary.	8.6074	0.9318720

Formula of Substance to be estimated.	Method of Estimation, etc.	Weight in Mgms. of Substance \div 1 c.cm. N Solution. $\frac{10}{10}$	Logarithm.
Salicylic acid and salicylates— (C ₆ H ₄ OHCOOK) ₂ + H ₂ O . C ₆ H ₄ OHCOONa + H ₂ O . C ₆ H ₄ OHCOOBiO . C ₆ H ₄ OHCOOBiO + H ₂ O .		3·08496 2·96843 6·0256 6·32593	0·4892504 0·4725272 0·7800051 0·8011246
Carbon disulphide and thiocarbonates— CS ₂ K ₂ CS ₃ Na ₂ CS ₃ (CH ₂) ₂ CS ₃ (C ₂ H ₅) ₂ CS ₃ C ₂ H ₅ KCS ₃	Absorb in alcoholic potash, neutralise or slightly acidulate with acetic acid, and all the CS ₂ will now be found as C ₂ H ₅ OCS ₂ SH titrate with iodine solution. I \equiv CS ₂ .	7·612 18·702 15·482 13·8768 16·68 17·691	0·8814988 1·2718881 1·1898271 1·1422393 1·2221960 1·2477524
Phenols, etc.— C ₆ H ₅ OH C ₆ H ₅ OK C ₆ H ₅ ONa C ₆ H ₅ CH ₂ OH C ₁₀ H ₇ OH C ₆ H ₄ (OH) ₂ C ₆ H ₅ CH ₂ (OH) ₂	Precipitate phenols from aqueous or dilute alcoholic solutions by excess of bromine (total quantity known), and estimate excess of Br by iodometric methods. Br \equiv I \equiv $\frac{1}{3}$ C ₆ H ₅ OH, etc.	1·56743 2·20316 1·93483 1·80108 2·50186 1·83413 2·06773	0·1951983 0·3430473 0·2866435 0·2555298 0·3982641 0·2634309 0·3154944

TABLE LXXVB (4).—Organic Substances containing Nitrogen.

Method of Estimation. Convert the nitrogen into ammonia and titrate against $\frac{N}{10}$ acid.

Many of the mononitrogenous bases can be estimated also by direct titration against $\frac{N}{10}$ acid: with such bases the factors given are applicable to either method.

Formula of Substance to be estimated.	Weight in mgms. of Substance \equiv 1 cm ³ . N Solution. $\frac{10}{10}$	Logarithm.	Formula of Substance to be estimated.	Weight in mgms. of Substance \equiv 1 cm ³ . N Solution. $\frac{10}{10}$	Logarithm.

LXXVB (7).—Estimation of some Isolated Alkaloids.

The alkaloid is treated with a known volume—somewhat in excess of what it requires to form a neutral salt—of N/50 acid; H_2SO_4 is best; and then the excess of acid is found by titrating with N/50 solution of NaOH or KOH.

The principal indicators are mentioned in the order of the reliability and sharpness of their indications.

Reference numbers to indicators—

1. Aikannin, $C_{15}H_{14}O_4$.
2. Azolithmin.
3. Cochineal.
4. Congo red, $C_{22}H_{25}N_6S_2O_6Na_2$.
5. Ethyl orange, $C_{16}H_{20}N_2SO_3$.
6. Hæmatoxyline, $C_{16}H_{14}O_6 + 3H_2O$.
7. Iodeosine, $C_{20}H_6O_5I_4K_2$.
8. Litmus.
9. Methyl orange, $C_{14}H_{16}N_3SO_3$.
10. Phenolphthalein, $C_{20}H_{14}O_4$.
11. Uranine, $C_{20}H_{10}O_5Na_2$.

Most alkaloids behave like monad radicles.

Strychnine,	$C_{20}H_{24}N_2O_2$	Against $KMnO_4$: $C_{14}H_{10}O_9 \equiv 24O$	10.6104	1.0257318
Tannin,	$C_{14}H_{10}O_9$	Against acid solution of I and KI. 1 mol. strychnine $\equiv 6I$	2.6778	0.4277781
Tolidine,	$C_8H_4(CH_3)N.H_2$	Against acid solution of I and KI. 1 mol. strychnine $\equiv 6I$	1.7852	0.2516869
Toluidine (o and p),	$C_6H_4(CH_3)N.H_2$	Against acid solution of I and KI. 1 mol. strychnine $\equiv 6I$	3.7528	0.5743554
" (p),	$C_6H_4(CH_3)N.H_2$	Against acid solution of I and KI. 1 mol. strychnine $\equiv 6I$	3.0056	0.4779312
Thymol,	$C_{10}H_{14}O$	Against acid solution of I and KI. 1 mol. strychnine $\equiv 6I$	8.4096	0.9247753
Urea,	$CO(NH_2)_2$	Against acid solution of I and KI. 1 mol. strychnine $\equiv 6I$	2.8032	0.4476541
Uric acid,	$C_5H_4N_4O_3$	Against acid solution of I and KI. 1 mol. strychnine $\equiv 6I$	3.9282	0.4811846
Xylidines,	$C_6H_5CH_3.CH_3.NH_2$	Each molecule of the compounds 1.2.4, 1.2.3, and 1.4.2 $\equiv 4Br$ Each molecule of 1.3.4 and 1.3.2 $\equiv 2Br$	6.0564	0.7822146

TABLE LXXVc.—Weights of Substances to be taken so that each Centigramme of Precipitate = 1% of Substance to be estimated.

By means of this table all calculations in connection with gravimetric estimations are dispensed with, *c.g.*—

(1) In an analysis of artificial manure the phosphates present are to be precipitated with magnesia mixture and weighed as $Mg_2P_2O_7$; if we want to know the percentage of P in the original manure, the table shows that we must take 0.2786 grm. of the original sample for analysis, and then each 0.01 grm. $Mg_2P_2O_7$ corresponds to 1 per cent. of P.

(2) To find the percentage of Ag in a silver coin by dissolving the coin in nitric acid, precipitating the silver as AgCl, washing, drying, and weighing.

The table shows that we should take 0.7527 grm. of the coin, then each centigramme of AgCl obtained \equiv 1 per cent. of Ag in the coin: thus, if the weight of AgCl obtained amounts to 0.9249 grm., the percentage of Ag in the coin would be 92.49.

The judicious use of this table will save busy analysts and assayers a vast deal of time and trouble, as the balance gives the percentages required.

One gramme of a substance yielded 2.4789 grms. BaSO₄: find the percentage of sulphur in the substance.

2 grms. = 27.4651 per cent. S.

.47 " = 6.4543 "

.0089 " = .1222 " ,

∴ 2.4789 = 34.0416 " ,

One centimetre cube of vitriol yielded 4.3697 grms. of BaSO₄: find the weight of H₂SO₄ in one litre of such vitriol.

4 grms. = 1680.39064 grms. per litre.

.36 " = 151.23516 " ,

.0097 " = 4.07495 " ,

∴ 4.3697 " = 1835.70075 " ,

9	250·5388	573·8147	1253·9062	1100·0108	946·1153

This table enables one to get at once, by simple addition, the percentage of P, P_2O_5 , etc., in a sample of manure or other phosphatic material: *e.g.* a gramme of a mineral yielded 0·6978 grm. of $\text{Mg}_2\text{P}_2\text{O}_7$; find the percentage of P_2O_5 in the substance

0·69 grm. $\text{Mg}_2\text{P}_2\text{O}_7$ corresponds to 43·9925 per cent. P_2O_5 .

·0078 " " " 1·973 " "

∴ 0·6978 " " " 41·4898 " "

One gramme of a phosphide yielded, on oxidation and precipitation, 2·7695 grm. of $\text{Mg}_2\text{P}_2\text{O}_7$; find the percentage of phosphorus in the sample

2· grms. of $\text{Mg}_2\text{P}_2\text{O}_7$ corresponds to 55·6753 per cent. of P.

·76 " " " 21·1566 " "

·0095 " " " 2·645 " "

∴ Percentage of P in the phosphide = 77·0964 " "

Percentage determinations can only be reliable to the second place of decimals in most cases.

TABLE LXXV D (3).—Assay Table.

Supposing a mineral yielded 0.007858 per cent. of fine gold, then the value of gold per ton of mineral is found as follows:—

0.007	corresponds to	£9 14 3.153
0.0008	„	1 2 2.417
0.00005	„	0 1 4.651
0.000006	„	0 0 1.998

Therefore 0.007858 „ „ £10 18 0.219

TABLE LXXV E (1).—Percentage of Na_2CO_3 in a mixture of Na_2CO_3 and K_2CO_3 .
 1 gram. $\text{K}_2\text{CO}_3 \equiv 144.61316$ c.cms. $\frac{N}{10}$ acid; 1 gram. $\text{Na}_2\text{CO}_3 \equiv 188.50141$ c.cms. $\frac{N}{10}$ acid.

If V = volume in c.cms. of $\frac{N}{10}$ acid used, then :—

Percentage of Na_2CO_3 in mixture = $(V - 144.61316) \times 2.278514$.

A difference of 0.01 c.cm. in V makes a difference of 0.0228 in the percentage of Na_2CO_3 ; in no case, then, can we rely on more than two places of decimals in the percentages.

V = c.cms. of $\frac{N}{10}$ acid corresponding to 1 gram.	Tenths of a cm. Cube.

TABLE LXXV (2).—Percentage of MgCO_3 in a mixture of MgCO_3 and CaCO_3 .

1 grm. $\text{CaCO}_3 \equiv 199·80020$ c.cms. $\frac{N}{10}$ acid; 1 grm. $\text{MgCO}_3 \equiv 237·07918$ c.cms. $\frac{N}{10}$ acid.

If V = volume in c.cms. of $\frac{N}{10}$ acid, neutralised by 1 grm. of the mixture, then:—

Percentage of MgCO_3 in mixture = $(V - 199·80020) \times 2·6824765$.

A difference of 0·01 c.cm. in V makes a difference of 0·0268 in the percentage of MgCO_3 ; so at best we cannot rely on anything beyond the second decimal.

V = c.cms. of $\frac{N}{10}$ acid corresponding to 1 grm.	Tenths of a cm. Cube.									
	·0	·1	·2	·3	·4	·5	·6	·7	·8	·9

TABLE LXXV_E (2).—*continued.*[illegible]

TABLE LXXV (3).—Percentage of CaCO_3 in a mixture of CaCO_3 and SrCO_3 .
 1 gm. $\text{SrCO}_3 = 135.50135$ c.cms. $\frac{N}{10}$ acid; 1 gm. $\text{CaCO}_3 = 199.80020$ c.cms. $\frac{N}{10}$ acid.

If V = volume of $\frac{N}{10}$ acid, neutralised by 1 gm. of mixture, then:—

$$\text{Percentage of } \text{CaCO}_3 = (V - 135.50135) \times 1.555238.$$

A difference of 0.01 c.cm. in V makes a difference of 0.0156 in the percentage of CaCO_3 : results to be relied on at best only to the second decimal.

V = c.cms. of $\frac{N}{10}$ acid corresponding to 1 gm.	Tenths of a cm. Cube.

TABLE LXXV_B (4).—Percentage of CaCO_3 in a mixture of CaCO_3 and BaCO_3 .
 1 gram. $\text{BaCO}_3 \equiv 101.31712$ c.cms. $\frac{N}{10}$ acid; 1 gram. $\text{CaCO}_3 \equiv 199.80020$ c.cms. $\frac{N}{10}$ acid.

If V = volume in c.cms. of $\frac{N}{10}$ acid, neutralised by 1 gram. of mixture, then:—

$$\text{Percentage of } \text{CaCO}_3 = (V - 101.31712) \times 1.0154028.$$

Here more reliance may, with very finely graduated burettes, be placed on the second decimal in the percentages, but nothing further can be relied upon.

V=c.cms. of $\frac{N}{10}$ acid correspond- ing to 1 gram.	Tenths of a cm. Cube.

199	99·19	99·29	99·39	99·49	99·59	99·70	99·80	99·90	100·00	*

The following mixtures are less likely to occur:—

MgCO₃ and SrCO₃; percentage of MgCO₃ = $(V - 135·50135) \times 0·9844668$.

MgCO₃ and BaCO₃; percentage of MgCO₃ = $(V - 101·317123) \times 0·7365828$.

SrCO₃ and BaCO₃; percentage of SrCO₃ = $(V - 101·317123) \times 2·9253253$.

TABLE LXXV_B (5).—Percentage of NaCl in a mixture of NaCl and KCl.

1 grm. KCl \equiv 134.048257 c.cms. of $\frac{N}{10}$ silver sol.; 1 grm. NaCl \equiv 170.940170 c.cms. $\frac{N}{10}$ silver sol.

If V = volume in c.cms. of $\frac{N}{10}$ silver solution corresponding to 1 grm. of mixture, then :—

$$\text{Percentage of NaCl} = (V - 134.048257) \times 2.7106211.$$

As one can work with a centinormal silver solution, and so get finer readings, the percentages are given to three places of decimals, but more than two can scarcely be relied upon.

V = c.cms. of $\frac{N}{10}$ Silver Solution corresponding to 1 grm.	Tenths of a cm. Cube.

If a gramme of the substance was taken, and the numbers in the first column denote centigrammes, then the numbers in columns 2 to 7 give percentages.

TABLE LXXV^E (12).—Weight in mgms. of $\text{Na}_2\text{S}_2\text{O}_3$ in a mixture containing $\text{Na}_2\text{S}_2\text{O}_3$ and Na_2SO_3 calculated from titrations of equal weights, (1) against N/10 KMnO_4 solution, and (2) against N/10 iodine.

Digest first portion with a known volume (excess) of KMnO_4 . After a time add a known volume (excess) of N/10 FeSO_4 solution and titrate back with N/10 KMnO_4 . Titrate the second portion against iodine in the usual way.

Putting (O) = volume in cm^3 of N/10 KMnO_4 actually used up by the mixture, *i.e.* total volume minus that corresponding to the FeSO_4 .

I = volume in centimetre cubes of N/10 iodine used.

One gramme $\text{Na}_2\text{S}_2\text{O}_3 \equiv 505.625 \text{ cm}^3$ N/10 KMnO_4 solution.

$\equiv 63.203$ „ „ iodine solution.

So weight of $\text{Na}_2\text{S}_2\text{O}_3 \equiv (\text{O} - \text{I}) \times 0.00226029 \text{ grms.}$

44	99.4526	99.6786	99.9046							

If 0.1 gram. of the substance was employed, then the numbers in this table give the percentages of $\text{Na}_2\text{S}_2\text{O}_3$. If only $\text{Na}_2\text{S}_3\text{O}_3$ and Na_2SO_3 be present, the weight of NaSO_3 is best obtained by subtracting the weight of $\text{Na}_2\text{S}_2\text{O}_3$ as given in the table from the weight of mixture used; when any other substance is present in the mixture, such other substance having no action on the standard solutions employed—then weight of $\text{Na}_2\text{SO}_3 = \frac{1}{7} (81 - O) \times 0.006308$.

0.1 gram. $\text{Na}_2\text{S}_2\text{O}_3 \equiv 50.5625 \text{ cm}^3$. $\text{N}/10\text{KMnO}_4 \equiv 6.3203 \text{ cm}^3$. $\text{N}/10\text{I}$.

TABLE LXXV (13).—Percentage of Na_2SO_4 in a mixture of K_2SO_4 and Na_2SO_4 calculated from the weight of BaSO_4 , corresponding to 1 grm. of the mixture.

1 grm. $\text{K}_2\text{SO}_4 \equiv 1.338954$ grm. BaSO_4 .

1 „ $\text{Na}_2\text{SO}_4 \equiv 1.642234$ „ BaSO_4 .

Weight of Na_2SO_4 per 1 grm. of mixture = $(W - 1.338954) \times 3.297281$, where

W = weight of BaSO_4 .

Weight of BaSO_4 Centigrammes.	Milligrammes.

TABLE LXXV_E (22).—Weights in mms. of various carbonates, etc., corresponding to 1 cm³ of dry CO₂ measured at 0° C.

	C.	Li ₂ CO ₃	Na ₂ CO ₃	K ₂ CO ₃	MgCO ₃	CaCO ₃	SrCO ₃	BaCO ₃	MnCO ₃	ZnCO ₃	CuCO ₃	PbCO ₃	Bi ₂ (CO ₃) ₃
In London under 760 mms.		0.539531	3.339111	4.770741	5.213363	3.743251	4.501001	6.636841	3.876100	5.170982	5.557680	12.001171	8.948044
In Lat. 45° under 760 mms.		0.539237	3.328173	4.738918	5.212551	3.731045	4.498385	6.632983	3.870941	5.167975	5.553339	11.994195	8.942843
Under 1 megadyne.		0.532246	3.254517	4.703345	5.134133	3.741622	4.439522	6.546680	3.755353	5.100694	5.561975	11.938504	8.826419

These numbers are all calculated from the actual density of CO₂ and not from the theoretical values. The results obtained by employing the theoretical value for the weight of 1 cm³ of CO₂ would be about 0.076 per cent. lower.

TABLE LXXV^e (23).—Percentage Composition of Mixtures of Two Pure Carbonates calculated from the Gain in Weight when all the CO₂ in one Gramme of the Mixture is replaced by SO₂.

Formula of First Carbonate.	Minimum Gain in Mgms.	Percentage of Second Carbonate for every Milligramme above the Minimum. Formula of Second Carbonate.

In ordinary laboratory practice only one decimal place in the "Minimum" column will be needed; three have been given in order to secure the best possible results where the gain per gramme of mixture is determined by calculation and not by direct experiment.

In the instances where the percentage numbers are marked by an asterisk (*) this method should never be employed; and in those marked + only when no more than a rough approximation is needed.

The following example shows how the table is to be used:—

In a mixture of BaCO₃ and ZnCO₃ the gain per gramme on replacing CO₂ by SO₂ was found to be 256.8 mgms., i.e. 256.8 - 182.7 = 74.1 above the minimum for pure BaCO₃.

On the same line as BaCO₃ in the column headed ZnCO₃ we find 0.9534, therefore
Percentage of ZnCO₃ in mixture = 0.9534 × 74.1 = 70.65.

TABLE LXXVE (24).—Percentage Composition of Mixtures of Two Pure Carbonates calculated from the Amount of CO_2 obtainable from one Gramme of the Mixture.

The principal use of the preceding table is for the determination, without separation, of the percentage composition of a mixture of two pure chlorides. The manner of using it can be best understood from the following instance:—

By operating with one gramme of a mixture of caesium chloride and lithium chloride 2.8756 grms. of silver chloride were obtained; find the percentage composition of the mixture.

If the whole gramme had been pure $LiCl$ we should have got 3.375235 grms. of $AgCl$

$CsCl$ " " 0.851172 " $AgCl$

Therefore for 100 per cent. of $LiCl$ we got above minimum 2.524063 " $AgCl$

and every mgm. of $AgCl$ above the minimum 0.851172 gm. corresponds to $\frac{100}{2524.063}$ per cent.

$LiCl$, i.e. to 0.03961866 per cent. $LiCl$.

The excess above minimum is $2.8756 - 0.8512 = 2.0244$ grms. or 2024.4 mgms.

∴ Percentage of $LiCl = 2024.4 \times 0.03961866 = 80.204$.

A mixture of two chlorides giving anywhere near the same amounts of $AgCl$ should not be tested by this method; the difference between maximum and minimum should be at least 0.1 gm.

Similar tables for sulphates, carbonates, etc., would prove useful in many cases, but the author has in course of computation a series of tables which practically does away with all calculations for mixture of any two pure salts. The following table is only a short excerpt from the table for two chlorides.

TABLE LXXV_E (26).—For the Determination of Percentage Composition of Mixtures of two Chlorides, without separation, and with practically no calculation.

W = Weight in grammes of mixture to be employed.

M = Amount to be subtracted from the weight (P) of AgCl obtained from W grms. of mixture.

Then the number of centigrammes in (P - M) gives the percentage of the chloride with the smaller equivalent.

NOTE.—Where W is so large as to be unmanageable, a half, a third, a fourth, etc., may be taken and P will then be twice, three times, four times, etc., the actual amount of AgCl obtained. When W is very large it may be taken in decigrammes, and each milligramme in (P - M) will then represent 1 per cent. of the second chloride.

Cyanogen,	2·333653	4·667306	7·000960	9·334613	11·668266	14·001919	16·335578	18·669226	21·002879
Prussic acid,	2·423988	4·847976	7·271965	9·695953	12·119941	14·543929	16·967917	19·391906	21·815894
Pot. cyanide,	5·842199	11·684397	17·526596	23·368795	29·210994	35·053192	40·895391	46·737590	52·579788
Urea,	2·693559	5·387118	8·080678	10·774237	13·467796	16·161355	18·854914	21·548474	24·242033
Uric acid,	3·768259	7·536517	11·304776	15·073084	18·841293	22·609551	26·377810	30·146068	33·914327
Albumen,	7·804215	15·608430	23·412645	31·216860	39·021075	46·825290	54·629505	62·433730	70·237935
Nitroglycerol,	6·786576	13·571753	20·357629	27·143506	33·929382	40·715259	47·501135	54·287012	61·072888

For example, 54·76 cm³. of gas saturated with aqueous vapour at 17° C. under 757 mms. pressure correspond, by Table LIX_H, to 54·76 × 0·917133 = 50·222203 cm³. of pure dry nitrogen at 0° C. under 760 mms. pressure; and this by Table LXXV_F (2), corresponds to 339·29382 + 1·35718 + 0·13572 + 0·01357 + 0·00136 + 0·00020 = 340·802 mms. of Nitroglycerol.

TABLE LXXVI.—ALCOHOLOMETRY.

A. Volume Percentage—measured at 15 $\frac{1}{2}$ ° C., 60° F., or 13 $\frac{1}{2}$ ° R.—according to the Reading of Tralles' Alcoholometer. (Brix.)

TABLE LXXVII.—Mass and Volume of Absolute Alcohol.

The accepted numbers representing absolute mass and volume must in all cases undergo thorough revision. About 1895 Mendelejeff recalculated the weight of a decimetre cube of water at various temperatures and obtained the following results, which seem to have been rather hastily legalised by the British Authorities.

Temperature.		Weight of Water in Vacuo.	
C.	F.	Dm. ³ in Grms.	In. ³ in Grains.
0°	32°	999·716	252·821
4	39·2	999·847	252·854
15	59	998·979	252·635
16 $\frac{2}{3}$	62	998·715	252·568
20	68	998·082	252·407

In 1900 the International Congress meeting at Paris accepted as the true mass of a decimetre cube of water at its maximum density the value found by MM. Guillaume and Chappuis, viz.,—

0·9999707 kgm.

The two values differ by a little less than 1 in 8000, or not quite 0·0125 per cent.

In 1899, Messieurs Fabry, de Lepinay and Perot had obtained the value,—

0·9999786 kgm.

Accepting the value sanctioned by the International Conference we get—

Mass of 1 cm.³ at 4° C. = 0·9999707 gramme.

Volume of 1 gramme at 4° C. = 1·0000293 cm. cubes.

The accepted values had previously been—

Mass of 1 cm.³ at 4° C. = 1·000013 grammes.

Volume of 1 gramme at 4° C. = 0·999987 cm. cube.

To calculate the new standard volumes from the old we have therefore to multiply by
1·0000423

and divide by the same number to get the new standard masses from the old ones.

“Absolute Alcohol,” i.e. a liquid completely composed of C_2H_5OH and holding practically no gases or other matter in solution, has probably never been prepared in any appreciable quantity.

Fownes gives the specific gravity of absolute alcohol as 0·7938, but it is rather uncertain whether this is to be taken as 15° C./4° C. or 60° F./60° F. Drinkwater found the sp. gr. 60° F./60° F. to be 0·79381.

The following give the specific gravity of “Absolute Alcohol” at 15° C., water at 4° C. being taken as unity.

Young, 0°/4°	.	.	0·80626	(1902)

Winkler’s details of purification, etc., certainly commend themselves most thoroughly to one’s confidence: he seems to have taken almost every conceivable precaution:—his

calculations barely show equal care. Recalculating from Winkler's experimental data the compiler gets the specific gravity of alcohol at $0^{\circ}/4^{\circ} = 0.806286$. This is very near the value found by Young, and on the whole one feels inclined to accept Winkler's results as practically final. For various reasons Squibb's results can barely be considered as ranking with those of Mendelejeff, Young, and Winkler.

The temperatures at which Winkler worked were 0° , $10^{\circ}.07$, $20^{\circ}.07$ and $30^{\circ}.07$ C., and using his weights, etc., obtained at those temperatures, and Guillaume and Chappuis' value for the maximum density of water, one gets:—

	Wt. of 1 cm. ³ in grammes.	Volume of 1 gm. in cm. cubes.
At 0°	0.80626248	1.24029088
10 .07	0.79773641	1.25354689
20 .07	0.78928400	1.26697108
30 .07	0.78068465	1.28092694

$$\text{And } V_t = V_0(1 + 0.00105819737t - 0.0005420024t^2 + 0.0003649746t^3) \quad . \quad . \quad (A).$$

Mendelejeff gives four values for the sp. gr. of his alcohol $0^{\circ}/4^{\circ}$ C. ;—

0.806263	(1)
0.806260	(2)
0.806250	(3)
0.806243	(4)

True mean 0.8062534.

This corresponds to

Mass of 1 cm.³ at 0° C. = 0.80622978 grammes.
Volume of 1 gm. at 0° C. = 1.24034119 cm. cubes.

Mendelejeff gives the sp. gr. of his alcohol ($t^{\circ}/4^{\circ}$) as follows:—

At 0°	= 0.806243
10 .38	= 0.797553
19 .95	= 0.789485
30 .83	= 0.780247

These give

$$V_t = V_0(1 + 0.00103462086t + 0.00014307957t^2 + 0.0002059062t^3) \quad . \quad (B).$$

Winkler gives the following formula—

$$\text{Sp. gr. } t^{\circ}/4^{\circ} \text{ C.} = 0.80629 - 0.000838t - 0.0004t^2$$

and this gives

$$V_t = V_0(1 + 0.0010393283t + 0.000108072t^2 + 0.0002253906t^3) \quad . \quad . \quad (C).$$

Taking others of Mendelejeff's determinations we get

$$V_t = V_0(1 + 0.0010333245t + 0.0001510972t^2 + 0.00009486t^3) \quad . \quad . \quad (D).$$

The four equations (A) to (D) are supposed to be appreciable from 0° C. to 30° C.

(One series of Mendelejeff's experiments only extend as far as $20^{\circ}.01$ C., and they give

$$V_t = V_0(1 + 0.001028418596t + 0.000244401685t^2 - 0.000337497963t^3) \quad (E); \quad 0^{\circ} \text{ to } 20^{\circ} \text{ C.}$$

Squibb's determinations are only sufficient to calculate two constants, and those only applicable between 0° and 25° C.; thus

$$V_t = V_0(1 + 0.00106883t + 0.000139569t^2).$$

If we accept Mendelejeff's own value for the density of water at 4° we get,—

Mass of 1 cm.³ of Absolute Alcohol at 0° C. = 0.80602442 gm.

Volume of 1 grammes " " " = 1.24065719 "

In the preceding, and many of the following calculated values, seven or eight places of decimals are given; this has been done simply to avoid introducing errors due to computation alone, but the correctness of any results cannot be relied on beyond .000001 at the very best; probably five decimals are the utmost that should be depended upon.

Finally, the compiler thinks that Winkler's value, say 0.80626 gm., may be safely accepted as the mass of 1 cm.³ of absolute alcohol at 0° C.; Mendelejeff's alcohol had a sp. gr. suspiciously low, and it got lower by keeping apparently. Klason and Norlin have recently obtained results agreeing very closely with Winkler's.

If the column headed "Kgms. of Absolute Alcohol" be taken to denote "Weight Percentage of Absolute Alcohol," the other columns will give, in litres, the volume of absolute alcohol obtainable from 100 kgms. of the spirit.

TABLE LXXVI_P.—Volume and Density of Aqueous Alcohol. * Calculated from Mendelejeff's Values for the Specific Gravity, and Guillaume and Chappuis' Constant.

This table is only applicable to solutions of pure cane sugar at 15° C., and, for all practical purposes, the number of grammes per litre divided by 16 will give in pounds avoirdupois the weight of sugar per cubic foot; or, divided by 100, they give weight of sugar per gallon of solution.

TABLE LXXVIIIc.—Sugar Contents of boiled Extracts of Grains, Syrups, etc. (Maumene.)

TABLE LXXVIII.—Water in Starch.

Starch containing more than 11·4 per cent. of water yields up the excess to alcohol of density 0·8339 (90° Tralles), and so the density of the alcohol becomes increased: should the starch contain less than 11·4 per cent., it speedily abstracts the deficit from the alcohol, and so reduces the density of the liquid. Scheibler calculated the table (1) from the density of alcohol (0·8339 originally) which had been shaken up with half its weight of starch (100 c.cms. of alcohol with 41·695 grms. of starch), and then filtered.

Saare rinses 100 grms. of potato starch to a tared flask of 250 c.cms. capacity, fills with water at 17·5 C., and then weighs again: the results obtained by him are given in table (2).

SUPPLEMENTARY TABLES.

WEIGHTS AND MEASURES.

The relative values of metric and imperial units are now legally fixed by "Orders of Council," and Regulations issued by the Board of Trade. These are based on careful comparisons of the standard yard, standard metre, etc., and they differ considerably from the older determinations on which the tables on pages 48-53 of Vol. I. were based. The following are extracted from the Regulations of the Board of Trade, dated March 1907:—

"The **Metre** is the length, at the temperature of 0° C., of the iridio-platinum bar numbered 16, deposited with the Board of Trade."

"The **Kilogram** is represented by the iridio-platinum weight, numbered 18, deposited with the Board of Trade."

"The **Litre** is represented by the capacity at 0° C. of the cylindrical brass measure marked 'Litre, 1897' (which is deposited with the Board of Trade)."

"The **Yard** is the length at 62° Fahr., marked on a bronze bar deposited with the Board of Trade."

"The **Pound** is the weight of a piece of platinum weighed in vacuo at 0° C., which is deposited with the Board of Trade."

"The **Gallon** contains 10 lbs. weight of distilled water weighed in air against brass weights, with the water and the air at the temperature of 62° Fahr., the barometer being at 30 inches."

The fundamental equivalents are given as follows:—

1 Metre (m.)	39·370113 inches.
1 Kilogramme	15·432·3564 grains.
1 Gallon	4·5459631 litres.

From these legalised equivalents the following tables have been carefully calculated:—

LINEAR MEASURES.

Imperial Linear Measures.

	Equivalent in Metres.	Log. of Equivalent.
1 inch	0·025400	2·4048333

VOLUME AND MASS OF WATER.

Recent investigations seem to indicate that the values accepted by the International Conference in 1900 (given on page 1183 *ante*) are slightly erroneous: the values considered most reliable are—

Mass of 1 cm.³ of pure water at 4° C. = 0.999972 gm.
Volume of 1 gm. of pure water at 4° C. = 1.000028 cm.³

The following table has therefore to be substituted for Table XLIA., in volume of this work :—

Volume and Density of Water between -10° C. and 100° C.

Temperatures according to Standard Mercury Thermometer.

The following table has been calculated on the assumption that the *relative* densities of water as given in Table XLIA. are fairly correct although the absolute densities are wrong :—

Temperature.	Weight of 1 cm. ³ in grms.	Vol. of 1 gm. in cm. ³	Temperature.	Weight of 1 cm. ³ in grms.	Vol. of 1 gm. in cm. ³

72	97671	02384	98	96002	04165
73	97612	02446	99	95931	04241
74	97552	02509	100	95860	04318
75	97492	02572			

Taking the legalised value for the metre (≈ 39.370113 in.) we get:

$$1 \text{ foot cube} = 28316.772668 \text{ cm.}^3$$

and, taking the weight in vacuo at 4° C. of 1 cm.³ of water to be 0.999972 gm., we get the weight of a foot cube of water in vacuo at 4° C. to be

$$28315.979799 \text{ grms.}$$

or

$$62.42604172 \text{ lbs. avoirdupois.}$$

This gives the weight in vacuo at 62° F. of 1 foot cube of water as

$$62.3558124 \text{ lbs.}$$

And the apparent weight against brass weights in air at 62° F. with the barometer at 30 inches is

$$62.288693 \text{ lbs. very nearly.}$$

The volume of water which, weighed against brass weights in air at 62° F. under a barometric pressure of 30 inches (ice-cold), has in London an apparent weight of 10 lbs., works out as

$$277.4179 \text{ cubic inches.}$$

With a barometric pressure of 30 inches of mercury at 62° F. the volume would be as nearly as possible 277·4202 cubic inches.

A cubic inch of water at 4° C. in vacuo weighs

252·88327 grains.

By these enactments all metric standards become empirical, and the ideal connection between the metre, litre, and gramme disappears: an imperial litre is practically 1000·16 cm.³ For practical purposes we may still assume that

1 litre = 1 decimetre cube,

and that 1 litre of water at 4° C. weighs 1 kilogramme.

Accepting 0·806286 as the specific gravity of absolute alcohol, 0°/4° C. (see page 1184), we get the

Mass of 1 cm.³ of Absolute Alcohol at ° C. = 0·80626342 grms.

Mass of 1 cubic inch of Absolute Alcohol at 32° F. = 203·896241 grains.

Taking the most probable meaning of the legal definition of a gallon—*i.e.* that “at the temperature of 62° F., the barometer being at 30 inches,” means at 30 inches of mercury at 62° F. and not 30 inches of ice-cold mercury—we get the

Capacity of the Imperial Gallon = 277·4202 cubic inches,

and 277·4202 cubic inches of ice-cold absolute alcohol would weigh

56564·936 grains.

8·080705 lbs. avoirdupois.

INDEX.

Method.—Where a table is devoted to one or two substances only, it is indexed under the substances and also under properties tabulated (viz. "Boiling Point," "Solubility," or such); where, however, table includes a large number of substances, it is indexed under property, and, where possible, the substances are grouped (viz. "Nitrates," "Acids, inorganic").

For greater convenience, volume is indicated before page number.

Organic compounds, liquid, expansion of, i. 150.
 solid, specific heats of, i. 197.
 solutions and mixtures, specific heats of, i. 201.
 substances containing nitrogen, estimation of, ii. 1102.
 volumetric analysis, ii. 1099.
 Oxides, solubility in water, ii. 932.
 Oxygen, volumes at various temperatures, i. 429.
 weight in U.K., U.S.A., and Colonies, i. 309.
 in foreign countries, i. 310.
 weight of, under various pressures, i. 314.
 π , multiples, etc. of, i. 56.
 Phosphates, analysis of, ii. 1123.
 boiling points of, ii. 810.
 solubilities of, in water, ii. 936.
 Phosphorus trichloride, vapour tension of, i. 473.
 Photometry, i. 26.
 Pipes, lead, weights of, i. 108.
 Plates, weights of metal, table of, i. 99.
 calculation of, from specific gravity, i. 100.
 Poiseuille's equation (viscosity), ii. 632.
 Potassium carbonate, specific gravity of solutions of, ii. 827.
 surface tension of, ii. 762.
 chlorate, boiling points and concentration, ii. 806.
 chloride, specific gravity of solutions of, ii. 877, 878.
 surface tension of, ii. 762.
 iodide, boiling points and concentration of solutions of, ii. 806.
 Potatoes, starch in, ii. 1203.
 Pressure of aqueous vapour, i. 329.
 solubility, and temperature, relations between, ii. 987.
 standards, corresponding value of various, i. 230.
 temperature, and latent heat of fusion, relations between, i. 403.
 volume, and temperature of gases, relation between, ii. 553.
 Pressures, conversion tables, i. 72.
 Prinsep's alloys, melting points of, i. 130.
 Propionic acid, boiling points under pressure, i. 522.
 vapour tension of, i. 492.
 Propyl acetate, vapour tension of, i. 497.
 alcohol, vapour tension of, i. 442.
 butyrate, vapour tension of, i. 449.
 formate vapour tension of, i. 496.
 iodides, vapour tension of, i. 505.
 isobutyrate, vapour tension of, i. 500.
 propionate, vapour tension of, i. 499.
 valerate, vapour tension of, i. 501.
 Prussian or Rhénish inches, equiv. in mm., i. 230.
 Pyrometers, Le Chatelier, i. 133 *et seq.*
 St Jacques, i. 132.
 Pyrometry, i. 130 *et seq.*

RÉAUMUR scale conversion to Fahrenheit and centigrade, i. 121.
 Reciprocals, i. 12.
 Refraction indices, i. 27.
 Rods and columns, table of weights, i. 101.
 SALT solutions, density of, i. 168.
 expansion of, i. 161.
 Secants, table of, i. 57.
 Sheet metal, calculation of weight from specific gravity, i. 100.
 table of weight of, i. 99.
 Silicon tetrachloride, vapour tension and specific volume of, i. 475.
 Silver, estimation of, in mixtures of silver salts ii. 1142 *et seq.*
 Slotte's equation (viscosity), ii. 626.
 Sodium carbonate solutions, specific gravity of, ii. 824 *et seq.*
 surface tension of, ii. 763.
 estimation of, in mixture with potassium carbonate, ii. 1133.
 chloride, estimation of, in mixture with potassium chloride, ii. 1141.
 surface tension of, ii. 761.
 sulphate, estimation of, in mixture with potassium sulphide, ii. 1153.
 thiosulphate, estimation of, in mixture with sodium sulphide, ii. 1151.
 Solids, surface tension of, ii. 800.
 velocity of sound in, ii. 569, 571.
 in metals, ii. 570.
 in alloys, ii. 570.
 in various solids, ii. 569.
 Solubility of acids in water, ii. 961.
 of bromides in water, ii. 929, 939, 989, 991.
 of carbonates in water, ii. 933, 948, 952, 976, 990.
 of chlorates in alcohol, ii. 964.
 in water, ii. 931, 961.
 of chlorides in alcohol, ii. 966, 967.
 in ammonia, ii. 981.
 in hydrochloric acid, ii. 969, 970, 971.
 in water, ii. 928, 937, 939, 940, 958, 971-978, 980, 982-984, 989, 991.
 of compounds at various temperatures, ii. 928 *et seq.*
 of gases in water, ii. 993 *et seq.*
 of iodates in water, ii. 931.
 of iodides in water, ii. 929, 940, 942, 956, 961, 989, 991.
 of mixed substances in mixed solvents, ii. 968.
 of nitrates in alcohol, ii. 964, 966, 967.
 in hydrochloric acid, ii. 973.
 in water, ii. 930, 940, 942, 944, 956, 974, 977, 978, 983, 984, 989.
 of oxides in water, ii. 932, 960.
 of phosphates in nitric acid, ii. 974.
 in water, ii. 936, 952.
 of substances in ethyl alcohol, ii. 962 *et seq.*
 of sulphates in alcohol, ii. 968.
 in hydrochloric acid, ii. 972, 973.
 in water, ii. 931, 944, 948, 957, 958, 974-980, 984, 989, 991.

Solubility of tartrates in water, ii. 938.
 relations of, to pressure and temperature, ii. 987.
 Solutions, boiling points and concentration of, ii. 802.
 capillarity constants of, ii. 756, 766, 770.
 compressibility, etc. of, ii. 786.
 preparation of, of known strength, ii. 985.
 specific gravity of some, ii. 814 *et seq.*
 surface tension of some, ii. 761 *et seq.*
 viscosity of, ii. 610.
 variation of, with temperature, ii. 625.
 Sound, velocity of, in air, ii. 572.
 in liquids, ii. 568.
 in solids, ii. 569.
 waves, speed of, ii. 564.
 Specific gravities and densities, estimation of, i. 220.
 and alcoholimetric readings, i. 228.
 and hydrometric readings, i. 224.
 gravity of solutions (various), ii. 814.
 of acetates, ii. 921-924.
 of acids, ii. 829-875.
 of alcohol, ii. 1190-1193, 1171-1179
 and ether (mixtures of), 1189.
 of bromates, ii. 901.
 of bromides, ii. 889.
 of cane sugar, ii. 1199.
 of chlorates, ii. 900.
 of chlorides, ii. 875 *et seq.*
 of fluorides, ii. 865.
 of glycerin, ii. 1194-1198.
 of iodates, ii. 901.
 of iodides, ii. 890.
 of nitrates, ii. 892-900.
 of sulphates, ii. 902-916.
 of tartrates, ii. 925.
 heat, formulae relating to, i. 206.
 of alloys, metals, etc., i. 183.
 of gases and vapours, i. 526.
 of inorganic compounds, solid, i. 187.
 solutions, i. 191.
 of mercury, i. 209.
 of minerals, i. 186.
 of organic compounds, solid, i. 196.
 solutions, i. 204.
 of water, i. 178-182.
 volume and vapour, density of ethyl alcohol, i. 443.
 Spheres, volumes of, i. 28.
 Square root, i. 28.
 Squares, table of, i. 28.
 Stannic chloride, vapour tension and specific volume of, i. 475.
 Starch in potatoes, ii. 1203.
 water in, ii. 1204.
 Steel, elasticity and torsion moduli, i. 86.
 Strength of beams, girders, etc., i. 71.
 of materials, i. 70.
 Stresses, conversion tables, i. 72.
 Sugar, content of boiled extracts of grains, syrups, etc., ii. 1203.
 solutions, viscosity of, ii. 652.
 weight of, corresponding to weights of cupric oxide, ii. 1205.

Sulphates, boiling points and concentration of, ii. 808.
 solubility of various, ii. 934, 944, 948, 957, 958, 974, 980, 984, 989, 991.
 specific gravity of, ii. 902-916.
 Sulphur compounds, analysis of, ii. 1120.
 vapour tension of, i. 471.
 Sulphuric acid, boiling, freezing, etc. points, ii. 859.
 per centage of sulphuric anhydride in, ii. 860.
 preparation of solutions of, ii. 861.
 specific gravity of, ii. 843-858, 862.
 Superficial measure, i. 50.
 Surface tension and capillarity, ii. 708.
 and chemical constitution, ii. 795.
 and other physical properties, ii. 785 *et seq.*
 between two liquids, ii. 773.
 influence of temperature upon, ii. 748.
 table of liquids, ii. 750.
 of alcohol, water, ether, and Benzol, ii. 725.
 of fused metals, ii. 776.
 of liquefied gases, ii. 781.
 sodium chloride, ii. 761.
 solids, ii. 800.
 various solutions, ii. 761 *et seq.*

TANGENTS, table of, i. 57.
 Tartrates, boiling points of, ii. 811.
 solubility of, ii. 938.
 specific gravity of, ii. 925.
 Temperature and expansion of bodies, i. 135 *et seq.*
 and pressure, and latent heat of fusion, i. 403.
 effect on diffusion of gases, ii. 665.
 on solubility and pressure, ii. 987 *et seq.*
 on solubility of various compounds, ii. 928.
 on specific gravity of hydrochloric acid, ii. 833.
 on surface tension, ii. 748.
 table of liquids, ii. 750.
 on viscosity of gases and vapours, ii. 582.
 on volume and pressure of gases, ii. 553.
 Temperatures, critical, i. 544.
 Thermal constants of gases, i. 278.
 Thermometers, comparison of air with alcohol, i. 129.
 with mercury, i. 129.
 of hydrogen with others, i. 129.
 of mercury with air, i. 128.
 Thermometric corrections, i. 123-126.
 readings, conversion of mercury to air, i. 126.
 conversion tables, i. 117-120.
 correction of, i. 122.
 Thermometry, i. 116.
 Thiosulphates, boiling points of solutions of, ii. 810.
 Time, measurement of, i. 48.
 Titration of acids, etc., ii. 1106.
 of basic substances, ii. 1107.

Toluol, vapour tension of, i. 507.
 Torsion moduli and elasticity for iron and steel, i. 86.
 of metals at various temperatures, i. 88.
 Trigonometrical formulae, i. 61.
 Tubes, brass, weights of, i. 109.
 copper, weights of, i. 109, 110, 111.
 Turpentine, vapour tension of, i. 508.

Vacuum, relation of weights in, to weights in air, i. 358.
 Vaporisation, latent heat of, i. 414.
 Vapour densities, i. 361.
 density of acetic acid, i. 442.
 of ethyl alcohol, i. 443.
 of methyl alcohol, i. 441.
 of propyl alcohol, i. 442.
 pressure of aqueous, i. 329.
 formulae for, of various substances, i. 514.
 tension and boiling point—determination of molecular weights, ii. 1028 *et seq.*
 tensions and boiling points of various substances, i. 451 *et seq.*

Vapours and gases, comparison of molecular and atomic heats of, i. 537.
 specific heats of, i. 526.
 and liquids, mutual relations between, i. 524.
 diffusion of, into air, hydrogen, and carbon dioxide, ii. 663.
 viscosity of, ii. 576.
 variation of, with temperature, ii. 582.

Viscosities, table of various substances, ii. 638.
 Viscosity and chemical structure, relations between, ii. 632.
 of alcohol, 0°-72°, ii. 636; 0°-60°, ii. 651.
 of bromine, ii. 637.
 of ethylic alcohol, ii. 650.
 of gases and vapours, ii. 576.
 variation with temperature, ii. 582.
 of inorganic acids, ii. 648.
 of liquids, ii. 635.
 variation with temperature, ii. 624, 646.
 mixed liquids and solutions, ii. 619.
 sugar solutions 1 to 30 per cent., ii. 632.
 Poiseuille's equation, ii. 632.
 Stokes's equation, ii. 626.

Volume and density of absolute alcohol, ii. 1187 *et seq.*
 measurement of, i. 51.
 temperature, and pressure of gases, ii. 553.

Volume, calculation of gaseous, i. 318.
 under standard pressure, table of, 320.

Volumetric analysis, ii. 1063.
 estimations, inorganic, ii. 1089.
 organic, ii. 1099, 1109.

WATER, boiling points under pressure, i. 454.
 expansion of, i. 167.
 capillarity constants of, ii. 714, 718.
 compressibility of, i. 93.
 in starch, ii. 1204.
 maximum density of, i. 166.
 under pressure, i. 167.

Water, solubility of ammonia in, ii. 1002.

of gases in, ii. 993 *et seq.*

of various substances, *See* Solubility.

specific heat of, i. 178-182.

surface tension of, ii. 725, 728.

viscosity of, ii. 635.

vapour tension of, i. 453.

volume and density of, i. 213-217, ii. 1225.

weight of, i. 215.

Water vapour, saturated, volume mass and pressure of, i. 462.

weights and pressures of, i. 311.

Weight, English measures of, i. 52.

Weight, metric measures of, i. 53.

Weights, measures, etc., i. 48, ii. 1221.

Wire, copper, table of weights, i. 107.

Wood spirit, specific gravity of, ii. 1190.

Work, data concerning, i. 65.

Wrought-iron tubes, weights of, i. 107.

XyloL, vapour tension of, i. 508.

Zinc, vapour tension of, i. 472.

chloride, specific gravity of, ii. 887.

sulphate, surface tensions of solutions of,
ii. 763.
